

3 Sustainable Management Criteria

3.1 Introduction to Sustainable Management Criteria and Definition of Terms

This section establishes the current and desired future SV Subbasin conditions through evaluation of the six sustainability indicators and outlines the analyses and processes used to define sustainable management criteria (SMC) for each sustainability indicator. Undesirable results, minimum thresholds (MTs), measurable objectives (MOs), and interim milestones (IMs) are defined for each sustainability indicator with respect to the quantification and avoidance of potential impacts on beneficial groundwater uses and users.

The following terms, defined below, are described for the SV Subbasin in the following sections.

Sustainability Goal: The overarching, qualitative goal for the Subbasin with respect to maintaining or improving groundwater conditions and ensuring the avoidance of undesirable results.

Sustainability Indicators (SI): The six categories of impacts to groundwater conditions identified by SGMA: lowering groundwater levels, reduction of groundwater storage, seawater intrusion, degraded groundwater quality, land subsidence, and surface water depletion. Undesirable results are defined as impacts determined as significant and unreasonable by the GSAs. Importantly, seawater intrusion is not applicable to the SV Subbasin and thus not discussed.

Sustainable Management Criteria (SMC): Minimum thresholds, measurable objectives, and interim milestones are quantitative criteria measured at a network of representative monitoring points (RMPs) that provide adequate coverage such that Undesirable Results, consistent with the sustainability goal, are avoided during the implementation period (through 2042) and beyond (after 2042).

Undesirable Results: Conditions, defined under SGMA as: “... one or more of the following effects to Sustainability Indicators caused by groundwater conditions occurring throughout a basin:

1. *Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply if continued over the planning and implementation horizon...*
2. *Significant and unreasonable reduction of groundwater storage.*
3. *Significant and unreasonable seawater intrusion.*
4. *Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies.*
5. *Significant and unreasonable land subsidence that substantially interferes with surface land uses.*
6. *Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water.”*

Minimum Thresholds (MTs): Quantitative values measured at RMPs that, if reached in accordance with the “Identification of Undesirable Results”, define the occurrence of an undesirable result. Thus, the management goal is to avoid groundwater conditions that exceed

41 MTs defined by this GSP. The term “minimum threshold” is predominantly used in SGMA
42 regulations and is applied to most sustainability indicators. The term “maximum threshold” is
43 equivalent but is used for sustainability indicators with a defined maximum limit (e.g.,
44 groundwater quality).

45 **Measurable Objectives (MOs):** Quantitative values measured at RMPs that maintain or
46 improve groundwater conditions and, if reached, represent the attainment of the basin’s
47 Sustainability Goal.

48 **Interim Milestones (IMs):** Quantitative periodic goals (defined every five years) that measure
49 progress towards the basin’s Sustainability Goal defined by the MOs.

50 **Representative Monitoring Points (RMPs):** For each SMC, RMPs are a sub-component
51 of the overall monitoring network which collectively “represent” hydrologic conditions that permit
52 the evaluation of sustainable groundwater management. SMC are measured at RMPs.

53 **3.2 Sustainability Goal (Reg. § 354.24)**

54 The overall Sustainability Goal of groundwater management in the SV Subbasin is to maintain
55 groundwater resources in ways that best support the continued and long-term health of the
56 people, the environment, and the economy of the SV Subbasin for generations to come. This
57 includes managing groundwater conditions for each of the applicable sustainability indicators in
58 the Subbasin so that:

- 59 • Groundwater elevations and groundwater storage do not significantly decline below their
60 historically measured range, protect the existing wells from outages, protect groundwater
61 dependent ecosystems, and avoid additional streamflow depletion due to groundwater
62 pumping.
- 63 • Groundwater quality is suitable for beneficial uses in the SV Subbasin and is not
64 significantly or unreasonably degraded.
- 65 • Significant and unreasonable land subsidence is prevented in the SV Subbasin.
66 Infrastructure and agriculture in the SV Subbasin remain safe from permanent
67 subsidence of the land surface.
- 68 • Significant and undesirable streamflow depletion due to groundwater pumping is avoided
69 through projects and management actions consistent with existing regulatory
70 requirements.
- 71 • The GSA groundwater management is effectively integrated with other watershed and
72 land use planning activities through collaborations and partnerships with local, state, and
73 federal agencies, private landowners, and other organizations, to achieve the broader
74 “watershed goal” of sufficient surface water flows that sustain healthy ecosystem
75 functions.

76 The Sustainability Goal will be achieved by rigorous assessment of potential impacts to
77 domestic, urban, agricultural, industrial, and environmental beneficial users, and scientifically-
78 informed management that avoids significant and unreasonable impacts to beneficial uses and
79 users of groundwater. This chapter defines and quantifies undesirable results for beneficial uses
80 and users of groundwater, which informs the SMC designed to avoid these undesirable results.

81 **3.3 Sustainable Management Criteria**

82 **3.3.1 Groundwater Elevation**

83 **3.3.1.1 Undesirable Results**

84 Chronic lowering of groundwater levels is considered significant and unreasonable when a
85 significant number of private, agricultural, industrial, or municipal production wells cannot pump
86 pump enough groundwater to supply beneficial uses. SGMA defines undesirable results related
87 to groundwater levels as chronic lowering of groundwater levels indicating a significant and
88 unreasonable depletion of supply if continued over the planning and implementation horizon.
89 The lowering of water levels during a period of drought is not the same as (i.e., does not
90 constitute) “chronic” lowering of groundwater levels if extractions and groundwater recharge are
91 managed as necessary to ensure that reductions in groundwater levels or storage are offset by
92 increases in groundwater levels or storage during other periods.

93 Potential impacts and the extent to which they are considered significant and unreasonable
94 were determined by the GSAs with input by technical advisors and members of the public.
95 During development of the GSP, potential undesirable results identified included:

- 96 ▪ Excessive number of domestic, public, or agricultural wells going dry.
- 97 ▪ Excessive reduction in the pumping capacity of existing wells.
- 98 ▪ Excessive increase in pumping costs due to greater lift.
- 99 ▪ Excessive need for deeper well installations or lowering of pumps.
- 100 ▪ Excessive financial burden to local agricultural interests.
- 101 ▪ Adverse impacts to environmental uses and users, including reduced interconnected
102 surface water (ISW) and decline of groundwater-dependent ecosystems (GDEs), or
103 undesirable levels of land subsidence.

104 To the best of our knowledge, never in the history of the SV Subbasin, even including the post-
105 2015 period, have any of the above undesirable results occurred, with the exception of ISW,
106 which has been impacted by groundwater pumping associated groundwater level declines. ISW
107 depletion is addressed in **Section 3.3.3**.

108 *3.3.1.1.1 Identification of Undesirable Results*

109 **Operationally, an undesirable result for groundwater level would occur if 25% of the fall**
110 **low groundwater level observation (i.e., the minimum groundwater level in any given**
111 **water year) in any of the RMPs fell below their respective MTs for two consecutive years.**

112 No further federal, state, or local standards exist for chronic lowering of groundwater elevations.

113 *3.3.1.1.2 Potential Causes of Undesirable Results*

114 Potential causes of Undesirable Results related to Chronic Lowering of Groundwater Levels
115 include increased pumping and/or reduced recharge.

116 The current primary use of groundwater in the SV Subbasin is for agriculture, thus increased
117 groundwater pumping could occur if water use per acre on irrigated land increases or if new
118 land is put into agricultural production. Similarly, although groundwater pumping for urban uses
119 is relatively small, additional urban development is expected within the Subbasin that could lead
120 to an increase in groundwater use.

121 Reduced recharge could occur due to increased agricultural irrigation efficiency and/or due to
122 climate change that could result in decreased precipitation, decreased surface water inflows

123 from contributing watersheds, reduced cross-boundary flows, and/or increased
124 evapotranspiration (ET).

125 Climate change is expected to increase average annual temperatures and intensify rainfall
126 events while also extending dry periods. Hence, during prolonged dry periods, climate change
127 may reduce runoff from surrounding uplands, thus reducing stream recharge to the Subbasin,
128 which may reduce groundwater levels provided constant extraction (**Chapter 2.2.3 Water**
129 **Budget**). However, during more intense wet periods, increased recharge and runoff in the
130 surrounding uplands may have the opposite effect and increase groundwater levels.

131 The GSAs will coordinate with relevant agencies and stakeholders within the SV Subbasin and
132 the larger watershed to implement management actions and projects to sustainably manage
133 groundwater levels in the Subbasin, and to forecast and understand how our evolving
134 understanding of climate change may inform and improve sustainable groundwater
135 management.

136 **3.3.1.2 Effects on Beneficial Uses and Users**

137 Undesirable results would prevent private, agricultural, industrial, or municipal production wells
138 from supplying groundwater to meet their water demands. Chronic well outages are not
139 expected in the SV Subbasin due to the lack of long-term overdraft and seasonal replenishment
140 of groundwater levels. These qualitative assessments are supported by quantitative well impact
141 analysis that suggests minimal impacts at proposed MTs.

142 The following provides greater detail regarding the potential impact of temporary well outages
143 on several major classes of beneficial users:

- 144 • **Municipal Drinking Water Users:** Undesirable results due to declining groundwater
145 levels can adversely affect current and projected municipal users, causing increased
146 costs for potable water supplies.
- 147 • **Rural and/or Agricultural Residential Drinking Water Users:** Seasonal low
148 groundwater levels can cause shallow domestic and stock wells to go dry, which may
149 cause seasonal well outages and restrict water access during periods of highest crop or
150 pasture water demand.
- 151 • **Agricultural Users:** Excessive seasonal lowering of groundwater levels could require
152 changes in irrigation practices and crop choice, which may cause adverse effects to
153 property values and the regional economy.
- 154 • **Environmental Uses:** Deep groundwater levels may result in significant and
155 unreasonable reduction of groundwater flow toward streams and impacts to groundwater
156 dependent ecosystems. This would adversely affect ecosystem functions related to
157 baseflow and stream temperature, as well as resident species.

158 **3.3.1.3 Relationship to Other Sustainability Indicators**

159 Minimum thresholds for groundwater elevation were designed to be consistent with the
160 avoidance of undesirable results for the other sustainability indicators. Groundwater levels are
161 directly related to groundwater storage, land subsidence, ISW depletion, and groundwater-
162 dependent ecosystems. The relationship between groundwater level MTs, and the MTs for other
163 sustainability indicators are discussed below.

- 164 • **Groundwater Storage:** Groundwater levels are closely tied to groundwater storage,
165 with high groundwater levels associated with high groundwater storage. The undesirable

166 result for groundwater storage is measured and thus defined as the occurrence of an
167 undesirable result for groundwater elevations.

- 168 • **Depletions of Interconnected Surface Water:** The magnitude and direction of
169 depletions of ISW depend on hydraulic gradients between the surface water and
170 adjacent groundwater. Hence, lowering groundwater levels that propagate to streams
171 may steepen hydraulic gradients and cause additional depletions of ISW that reduce in-
172 stream flows, prevent fish migration and/or spawning, impact riparian ecosystems, and
173 reduce surface water availability for downstream beneficial users of surface water with
174 riparian or appropriative surface water rights. These beneficial users of surface water
175 may be GSAs and associated users within or outside of the Subbasin.
- 176 • **Seawater Intrusion:** This sustainability indicator is not applicable in the SV Subbasin.
- 177 • **Groundwater Quality:** A significant and unreasonable condition for degraded water
178 quality is exceeding drinking water standards for constituents of concern in supply wells
179 due to projects and management actions proposed in the GSP. Although seasonal
180 lowering of groundwater level minimum thresholds does not directly affect water quality,
181 groundwater quality could potentially be affected by projects and management action-
182 induced changes in groundwater elevations and gradients. These changes could
183 potentially cause poor quality groundwater to flow towards supply wells that would not
184 have otherwise been impacted.
- 185 • **Subsidence:** The groundwater level SMC ensures the avoidance of worsening future
186 subsidence. Groundwater level MTs are sufficiently close to historic groundwater levels,
187 and historically-observed land subsidence was not significant and unreasonable. Thus,
188 significant subsidence resulting from lowering groundwater levels to MTs is not
189 anticipated.

190 **3.3.1.4 Information and Methodology Used to Establish Minimum Thresholds and** 191 **Measurable Objectives, and Interim Milestones**

192 Groundwater level SMC represent the analysis of best-available data at the time of writing and
193 will be evaluated in subsequent plan updates. In establishing MTs for groundwater level decline,
194 the following information was considered:

- 195 • Feedback about groundwater level decline concerns from stakeholders.
- 196 • An assessment of available historical and current groundwater level data from
197 monitoring wells in the Subbasin.
- 198 • An assessment of trends in groundwater level at selected wells with adequate data to
199 perform the assessment.
- 200 • Potential impact to ISW, GDEs, and wells at various groundwater level conditions.
- 201 • Input from stakeholders resulting from the consideration of the above information in the
202 form of recommendations regarding MTs and associated management actions.

203 MTs for groundwater levels were then determined by historical analysis of groundwater level
204 monitoring data from January 2000 to June 2021, setting preliminary SMC, evaluating the
205 impact of those SMC on beneficial users of groundwater (e.g., ISW, GDEs, wells), and iterating
206 on the SMC until significant and unreasonable impacts were avoided.

207 Importantly, undesirable results due to excessive lowering of groundwater levels have not been
208 historically observed in the SV Subbasin, which implies that groundwater levels near historical
209 lows should not cause undesirable results.

210 To establish SMC a three-step process was followed at each representative monitoring point
211 (RMP). First, the January 2000 to current trend of groundwater levels were linearly projected to
212 January 2032, corresponding to 10 years after GSP submission. Second, the projected
213 groundwater level was compared to the lowest groundwater elevation observed after
214 January 2015. Third, the minimum of the values compared in step two were then reduced by a
215 buffer equal to 10% of the January 2000 to current range of groundwater levels observed at
216 each monitoring point to arrive at the MT. MTs were then rounded down to the nearest integer
217 to ease interpretability. RMPs that show an increase in groundwater level use the observed
218 minimum level as the MT. These SMC effectively give the Subbasin time to respond to
219 corrective action. The 10% buffer allows for operational flexibility to account for potential
220 extreme climate conditions and to accommodate practicable triggers. The analysis for the RMPs
221 is presented in **Figure 3.3.1-1**. On the figure, the measured groundwater levels are black solid
222 lines, the MT is represented as a red horizontal solid line, the MO is shown as a blue horizontal
223 solid line, and the IMs are grey horizontal dashed lines. The two vertical green dashed lines on
224 each sub-plot demark January 2015 and January 2032. Note that all subplots share the same
225 x-axis, but have different y-axis scales. RMPs capture the shallow and deep zones of the
226 aquifer.

227 Next, these MTs were assessed in terms of potential impact to various beneficial users of
228 groundwater including shallow wells (e.g., domestic, public, agricultural, and industrial),
229 groundwater dependent ecosystems, and interconnected surface water.

230 1. **Avoidance of impacts to shallow wells:** An MT groundwater surface was simulated
231 based on the projected groundwater level decline implied by MTs, and combined with
232 well completion report data to estimate impacts to wells. Assuming all MTs are
233 simultaneously reached across the basin – a theoretical worst case and unlikely
234 scenario – only 6 to 10 domestic wells (2%) are impacted, and no other well types are
235 impacted. This finding is consistent with the fact that most wells are relatively deep
236 compared to present-day groundwater levels and groundwater level MTs. Thus, the MTs
237 presented herein protect shallow wells. A detailed discussion of the well impact analysis
238 is presented in **Appendix 3A**.

239 2. **Avoidance of impacts to GDEs:** MOs and MTs for each well were evaluated in terms
240 of their impact on GDEs. Where there were no GDEs within a 1-mile radius of the
241 monitoring point the MO and MT were not changed. Because there is no record of the
242 extent of GDEs through time, the NDVI of mapped GDE polygons was used to assess
243 the linkage between groundwater elevation and GDE health. If a statistically significant
244 relationship exists between depth to groundwater and NDVI the potential impact of MO
245 and MT values was assessed for the monitoring well. For wells screened at more than
246 one depth, only the shallowest screening interval was used. The degree to which NDVI
247 recovered following water elevations close to the MT was investigated to ensure that
248 historical water elevations near the MT did not negatively impact the GDEs (**see Chapter
249 2 for details on GDE NDVI**). Where possible, MTs were adjusted to be within the
250 historical range of groundwater elevations so that the impact on GDEs was known. For
251 riverine GDEs, the MT was adjusted to within 10 ft of the ground to promote ISW where
252 reasonable.

253 Based on a review of historical NDVI and water surface elevation, MOs and MTs were
254 adjusted at 4 wells to conservatively limit impacts to GDEs (RMP IDs 93, 209, 291, and

255 300). The remainder of the wells either had no GDEs within 1 mile of the RMP, did not
256 have a statistically significant relationship between NDVI and groundwater elevation, had
257 groundwater depths > 30 ft below ground surface, or had relatively robust NDVI at the
258 MO and MT. For RMP 93, groundwater elevations at or below the previous MT caused
259 declines that persisted for more than 1 year. The MT was raised by 1 ft to a groundwater
260 elevation above this threshold where impacts to NDVI did not persist. The MO was
261 increased by 1 ft RMP 93 to more closely reflect the minimum groundwater elevation at
262 which NDVI reached its highest value (0.6). Because RMP 93 is adjacent to the large
263 wetland in the western portion of the basin, the MO and MT were conservatively
264 adjusted to limit impacts to this GDE, despite the large depth of the well.

265 For RMP 209 the MO was adjusted to be within 10 ft of the ground surface to support
266 ISW. For RMP 291 the MO and MT were adjusted by < 1ft. The MO was adjusted to 6 ft
267 below ground surface to reflect high groundwater levels in 2006, 2017, and 2019.
268 Finally, the MT was increased to 10ft below ground surface to support ISW. For RMP
269 300, the MT was adjusted to the 2010-2015 low value and the MO not changed. This
270 well only has groundwater data from 2005-present and more detailed monitoring of GDE
271 health relative to groundwater elevation will help to understand linkages between GDEs
272 and groundwater elevation at this site.

273 3. **Avoidance of impacts to ISW:** Groundwater level MTs near interconnected surface
274 water (ISW) are set no lower than historically observed low groundwater levels to arrest
275 hydraulic gradients and prevent ISW depletion that exceeds previously experienced
276 depletion (**Section 3.3.3.4**). The difference between Fall 2015 groundwater levels and
277 MTs varies by location in the basin, and ranges from 0 to 13 feet as displayed on
278 Figure 3.3.1-2.

279 Next, measurable objectives (MOs) were defined as the average groundwater elevation
280 observed after 2015-01-01, which correspond to present-day groundwater levels and imply a
281 management goal to maintain these levels. MOs were rounded to the nearest integer to ease
282 interpretability. Operational flexibility is defined as the difference between the MO and the MT.
283 Interim milestones (IMs) were defined as regular five-year long intervals between the MT and
284 MO at 2027, 2032, and 2037. The MO can be understood as the 4th and final IM. When the
285 operational flexibility for and RMP is less than 3 feet, due to nearest-integer-rounding, one or
286 more IMs will be equal to the MO.

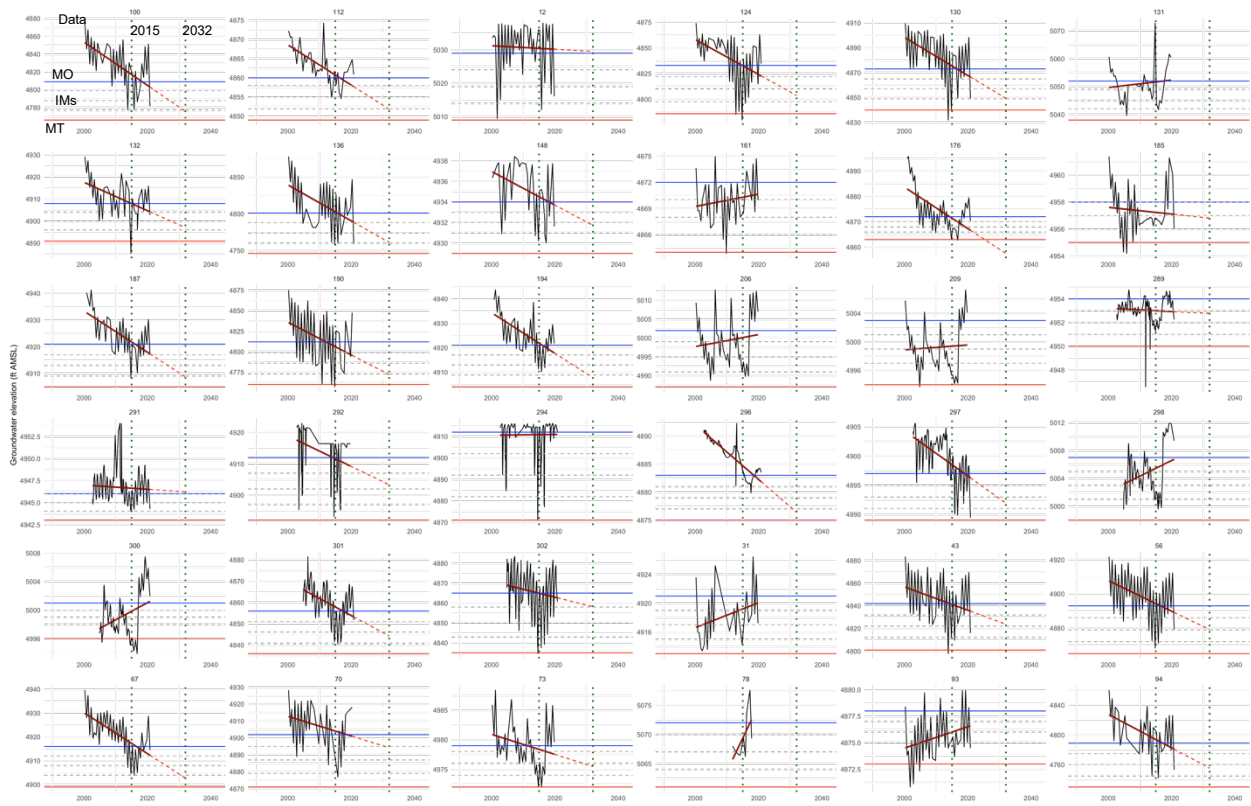

287 3.3.1.4.1 Triggers

288 The primary trigger for management actions will be if groundwater levels fall below historic lows
289 in any individual well for more than two consecutive years – notably, this does not constitute an
290 undesirable result, but warrants attention. A secondary trigger for management actions will be if
291 2% (n = 6) of domestic well outage reports are received. This trigger value is based on findings
292 that suggest 2% of domestic wells may be impacted assuming MTs across the entire basin are
293 reached at the same time (Technical Appendix 3A). If either of these triggers occur, the GSAs
294 will investigate and reassess SMC suitability and may use management actions to proactively
295 avoid the occurrence of undesirable results.

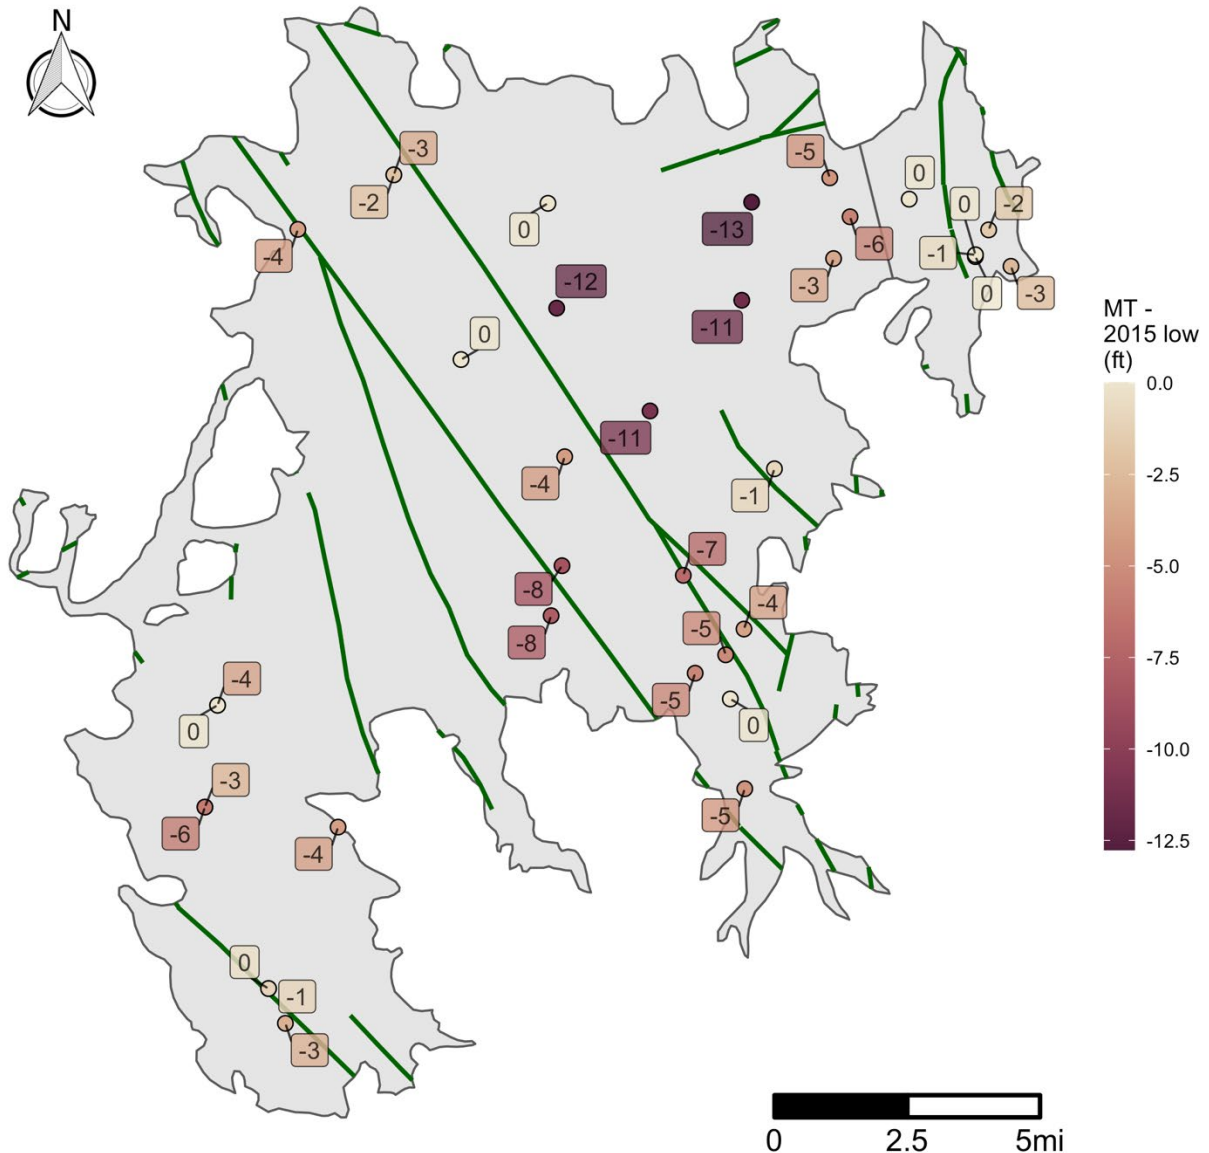

296
297

Figure 3.3.1-1. Analysis of Historical Groundwater Levels at the Representative Monitoring Points and the Minimum Thresholds and Measurable Objectives

298 **Figure 3.3.1-2. Minimum thresholds do not substantially lower groundwater elevations beyond the**
 299 **lowest recorded values (Fall 2015) and maintain elevations above historic lows near ISW.**

300 **3.3.1.4.2 Method for Quantitative Measurement of Minimum Thresholds**

301 The groundwater elevation at each RMP will be monitored quarterly to directly assess the SMC.
 302 The RMPs and associated SMC are listed in **Table 3.3.1-1** and presented spatially in
 303 **Figure 3.3.1-3**. Note that in some instances, multiple wells are included at the same location
 304 (e.g., nested wells). These wells are denoted by duplicate labels in the figure and have unique
 305 RMP IDs as well as unique screened intervals. These monitoring locations are unique in that
 306 they capture shallow and deep aquifer zones.

307
308

Table 3.3.1-1. Representative Monitoring Point (RMP) Elevations and Minimum Thresholds (MTs) and Measurable Objectives (MOs)

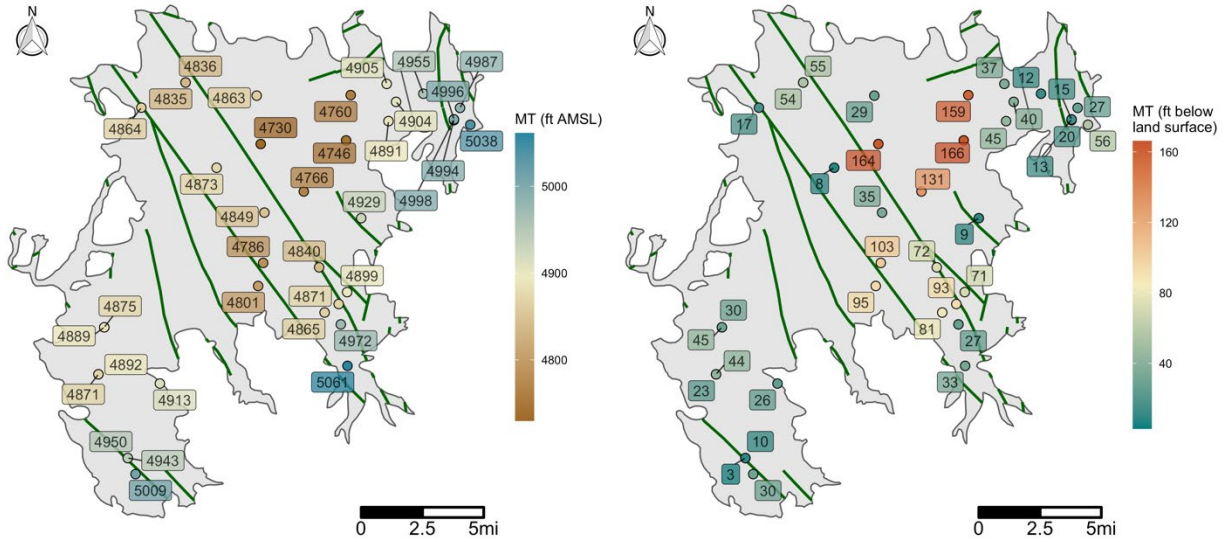

| RMP ID | Site Code | Ground Surface (ft AMSL) | Water Surface ⁽¹⁾ (ft AMSL) | MO (ft AMSL) | MT (ft AMSL) |

Figure 3.3.1-3. Minimum Thresholds in elevation above mean sea level (left) and below land surface (right) for the Representative Monitoring Points (duplicate labels indicate nested monitoring wells)

313 **3.3.1.5 Measurable Objectives**

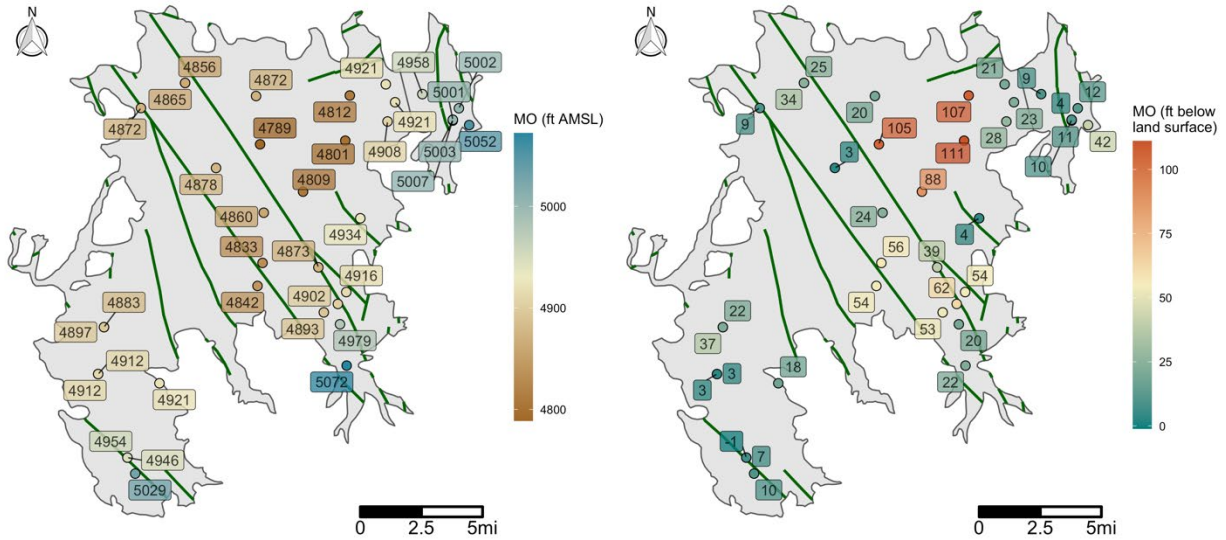

314 The groundwater elevation MOs for the SV Subbasin are set to represent the current condition
315 of the Subbasin and correspond to management goals that maintain these levels.

316 **3.3.1.5.1 Description of Measurable Objectives**

317 For all RMPs, MOs are set to the average water level observed from January 2015 to
318 June 2021. Each MO was rounded to the nearest integer to ease interpretation. The MOs are
319 listed for each RMP in **Table 3.3.1-1** and presented in **Figure 3.3.1-4**.

320
321
322

Figure 3.3.1-4. Measurable Objectives in elevation above mean sea level (left) and below land surface (right) for the Representative Monitoring Points (duplicate labels indicate shallow and deep wells at the same location)

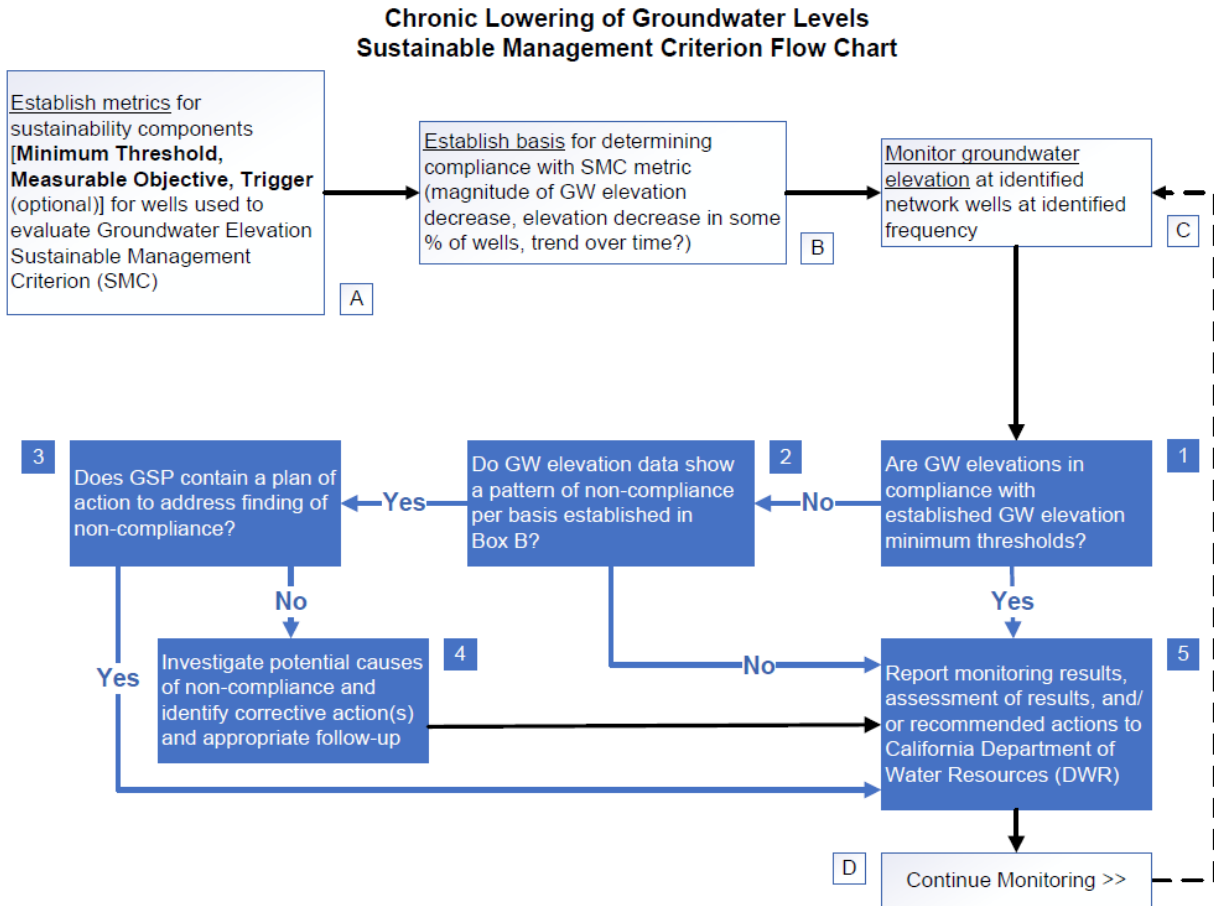

323 **3.3.1.6 Path to Achieve Measurable Objectives**

324 The GSAs will support achievement of the MOs by monitoring groundwater levels and
 325 coordinating with agencies and stakeholders within the Subbasin to implement projects and
 326 management actions. The GSAs will review and analyze groundwater level data to evaluate any
 327 changes in groundwater levels resulting from groundwater pumping or recharge projects in the
 328 Subbasin. Using monitoring data collected as part of GSP implementation, the GSAs will
 329 develop information (e.g., hydrograph plots) to demonstrate that projects and management
 330 actions are operating to maintain or improve groundwater level conditions and to avoid
 331 unreasonable groundwater levels. Should groundwater levels drop to a trigger or MT as the
 332 result of GSAs project implementation, the GSAs will implement measures to address this
 333 occurrence. This process is illustrated in **Figure 3.3.1-5** based on a combination of monitoring,
 334 reporting, investigation, and when necessary, corrective actions.

335 To manage groundwater levels, the GSAs will partner with local agencies and stakeholders to
 336 implement projects and management actions. Projects and management actions are presented
 337 in further detail in Chapter 4. Implementation timelines and approximate costs are discussed in
 338 Chapter 5. Examples of possible GSAs actions include stakeholder education and outreach and
 339 support for impacted stakeholders.

340 Where the cause of groundwater level decline is unknown, the GSAs may choose to conduct
 341 additional or more frequent monitoring or initiate additional modeling. The need for additional
 342 studies on groundwater levels will be assessed throughout GSP implementation. The GSAs
 343 may identify knowledge requirements, seek funding, and help to implement additional studies.

Figure 3.3.1-5: Groundwater Level Sustainable Management Criteria Flow Chart

345 **3.3.1.6.1 Interim Milestones**

346 Interim milestones (IMs) were defined as regular 5 year long intervals between the MT and MO
 347 at 2027, 2032, and 2037. The MO can be understood as the fourth and final IM. When the
 348 operational flexibility for and RMP is less than 3 feet, due to nearest-integer-rounding, one or
 349 more IMs will be equal to the MO.

350 **3.3.2 Groundwater Storage**

351 Chronic lowering of groundwater levels is directly correlated with reduction of groundwater
 352 storage. Groundwater storage is the three-dimensional equivalent of groundwater level (one-
 353 dimensional) over an area. Reduction in groundwater storage generally indicates groundwater
 354 level decline, and vice versa. Thus, groundwater levels may be used as a proxy for groundwater
 355 storage, and the potential causes and identification of Undesirable Results related to reduction
 356 in groundwater storage are identical to those related to chronic lowering of groundwater levels
 357 (Section 3.3.1.1).

358 GSAs will track and project groundwater storage with the Sierra Valley integrated hydrologic
 359 model, and calibrate groundwater storage estimates based on data collected throughout the
 360 Subbasin. As before, potential effects of Undesirable Results on beneficial uses and users of

361 groundwater due to reduced groundwater storage are identical to those outlined due to chronic
362 lowering of groundwater levels (**Section 3.3.1.2**), as are SMC (**Sections 3.3.1.4 - 3.3.1.6**).

363 **3.3.3 Depletion of Interconnected Surface Waters**

364 **3.3.3.1 Undesirable Results – Depletion of Interconnected Surface Water**

365 Significant and unreasonable depletion of interconnected surface water (ISW) due to
366 groundwater extraction is identified if ISW depletion exceeds the maximum depletion rates
367 indicated in the monitoring record from January 2000 to January 2021. Notably, these rates
368 have not yet been calculated, pending the results of the Sierra Valley integrated hydrologic
369 model. However, this GSP acknowledges that ISW depletion is occurring, but this depletion is
370 not significant and unreasonable, and then takes the conservative approach of not worsening
371 ISW gradients and hence, not causing unexperienced effects on the Subbasin. These
372 management objectives are quantitatively achieved by arresting groundwater levels near ISW at
373 historical levels, which thereby arrests hydraulic gradients and ISW depletion.

374 *3.3.3.1.1 Potential Causes of Undesirable Results*

375 Depletion of ISW is related to chronic lowering of groundwater levels via changes in the
376 hydraulic gradient. Darcy's Law is a fundamental tenet of groundwater hydrogeology that
377 explains this.¹ It states that the amount of water that flows through an aquifer (e.g., ISW
378 depletion) is proportional to the hydraulic gradient (in this case, the difference between the
379 water surface elevation in the stream ('stage') and adjacent groundwater elevation). Hence,
380 declines in groundwater level which increase the hydraulic gradient between the ISW and the
381 aquifer also increase ISW depletion.

382 Undesirable Results related to ISW depletion could be caused by increased pumping and/or
383 reduced recharge (e.g., due to drought, climate change, or changes in irrigation rates or
384 practices). Most of the pumped groundwater in the basin is used for agriculture; therefore,
385 increased demand per irrigated acre or an increase in irrigated acreage could result in
386 depletions to surface water. Natural and managed variability in the timing and magnitude of
387 inter- and intra-basin diversions could also affect recharge and available surface water and lead
388 to ISW depletion. Efforts to move from flood irrigation (commonly practiced on the south and
389 west sides of the valley) to spray irrigation could increase irrigation efficiency but also potentially
390 reduce recharge, leading to lower groundwater level and hence, ISW depletion. The inter-basin
391 diversion from the Little Truckee River supplies substantial surface water (6,693 acre-feet on
392 average from 1959 to 2020) to Sierra Valley during the irrigation season. In a warming climate,
393 reduced snowpack and spring and summer runoff could affect the availability of water from the
394 Little Truckee Diversion. Other factors related to climate change such as decreased
395 precipitation and increased evapotranspiration could also lead to ISW depletion.

396 **3.3.3.2 Effects on Beneficial Uses and Users**

397 Undesirable Results would have the greatest impact to agricultural and environmental uses and
398 users. Agricultural users in the southern and western portions of the valley rely heavily on
399 surface water to irrigate pasture. Ongoing or increased groundwater pumping could alter the
400 horizontal and vertical gradients that affect the rates and direction of groundwater flow. Streams
401 and wetlands may switch from gaining to losing if groundwater levels decline past critical

¹ Darcy's Law, $Q = K \cdot A \cdot i$ states that the volumetric rate of flow Q is proportional to the hydraulic conductivity (K , or resistance to flow), the cross-sectional area (A , in this case, of the streambed), and the hydraulic gradient i (in this case, the difference between water surface elevation in the stream ('stage') and adjacent groundwater level). Thus, as the difference between stream stage and groundwater level increases, the hydraulic gradient (i) increases, which makes streamflow depletion (Q) increase.

402 thresholds, which would result in less available surface water for irrigation, and stream losses
403 into shallow aquifers.

404 ISW provides habitat for priority species, thus ISW depletion may impact these beneficial users.
405 Late summer and early fall are particularly important, as some ISW streams may depend on late
406 season groundwater discharge to support baseflow when snowmelt and surface runoff are at a
407 minimum. ISW depletion would not only the availability, but also the quality of habitat. In late
408 summer and fall conditions, upwelling of relatively cool groundwater helps maintain surface
409 water temperature from warming excessively and negatively impacting priority species. In the
410 Sierra Valley, how ISW depletion could impact sensitive species is poorly understood.
411 Monitoring of species diversity, populations, and available habitat occurs, but is insufficient to
412 fully understand the impacts of ISW depletion on such environmental systems. Widespread
413 monitoring and documentation needs are discussed further in **Section 3.4.1.4**.

414 **3.3.3.3 Relationship to Other Sustainability Indicators**

415 Minimum thresholds (MTs) established for the depletion of interconnected surface water are the
416 most conservative of the sustainability indicators, in that they do not allow for future conditions
417 that exceed historically observed ISW depletion.

418 Increased ISW depletion results from chronic lowering of groundwater levels when lowering
419 groundwater levels leads to an increase in the stream-aquifer hydraulic gradient, and hence,
420 increased depletion. Therefore, by effectively managing groundwater levels that avoid lowering
421 groundwater levels, ISW depletion can also be managed. Moreover, monitoring and forecasting
422 basin-wide storage also provides a big picture view of how ISW depletion may be impacted,
423 although spatially distributed changes in groundwater level are much more useful in isolating
424 local-scale ISW impacts.

425 The chronic lowering of groundwater level SMC allows for lowering to the minimum level seen in
426 a linear trend of groundwater levels since January 2000 and projected out to 2032 plus an
427 additional 10% of the range. In contrast, in ISW zones, groundwater level MTs are adjusted
428 consistent with ISW MTs, such that no additional groundwater level depletion occurs in excess
429 of historical impacts (i.e., observed between January 2000 and January 2021).

430 **3.3.3.4 Information and Methodology Used to Establish Minimum Thresholds and** 431 **Measurable Objectives**

432 **3.3.3.4.1 Groundwater Elevations as a Proxy for Depletion of Interconnected Surface Water** 433 **Minimum Thresholds**

434 Depletion of Interconnected Surface Water as a volume or rate is difficult to quantify in Sierra
435 Valley due to data gaps. Groundwater monitoring data is lacking near ISW, and there are no
436 continuous streamflow or stage gages within the basin. Data collected by the DWR
437 Watermaster for the Sierra Valley is only done in preparation for and during the irrigation season
438 with periodic measurements on up to 12 different tributaries. Due to the discontinuous nature of
439 these measurements, simple mass-balance approaches to ISW depletion estimation are
440 infeasible.

441 Quantification of ISW depletion is in development and will be achieved through the use of the
442 Sierra Valley integrated surface water-groundwater model. Two different scenarios will be
443 evaluated: with and without pumping. All other model inputs will remain the same between the
444 two scenarios. Streamflow results will be compared, and the difference, measured as a volume
445 or rate, is the amount of surface water depletion due to groundwater pumping. In lieu of results
446 from this integrated surface and groundwater model, we conservatively set ISW SMC to arrest
447 hydraulic gradients near ISW.

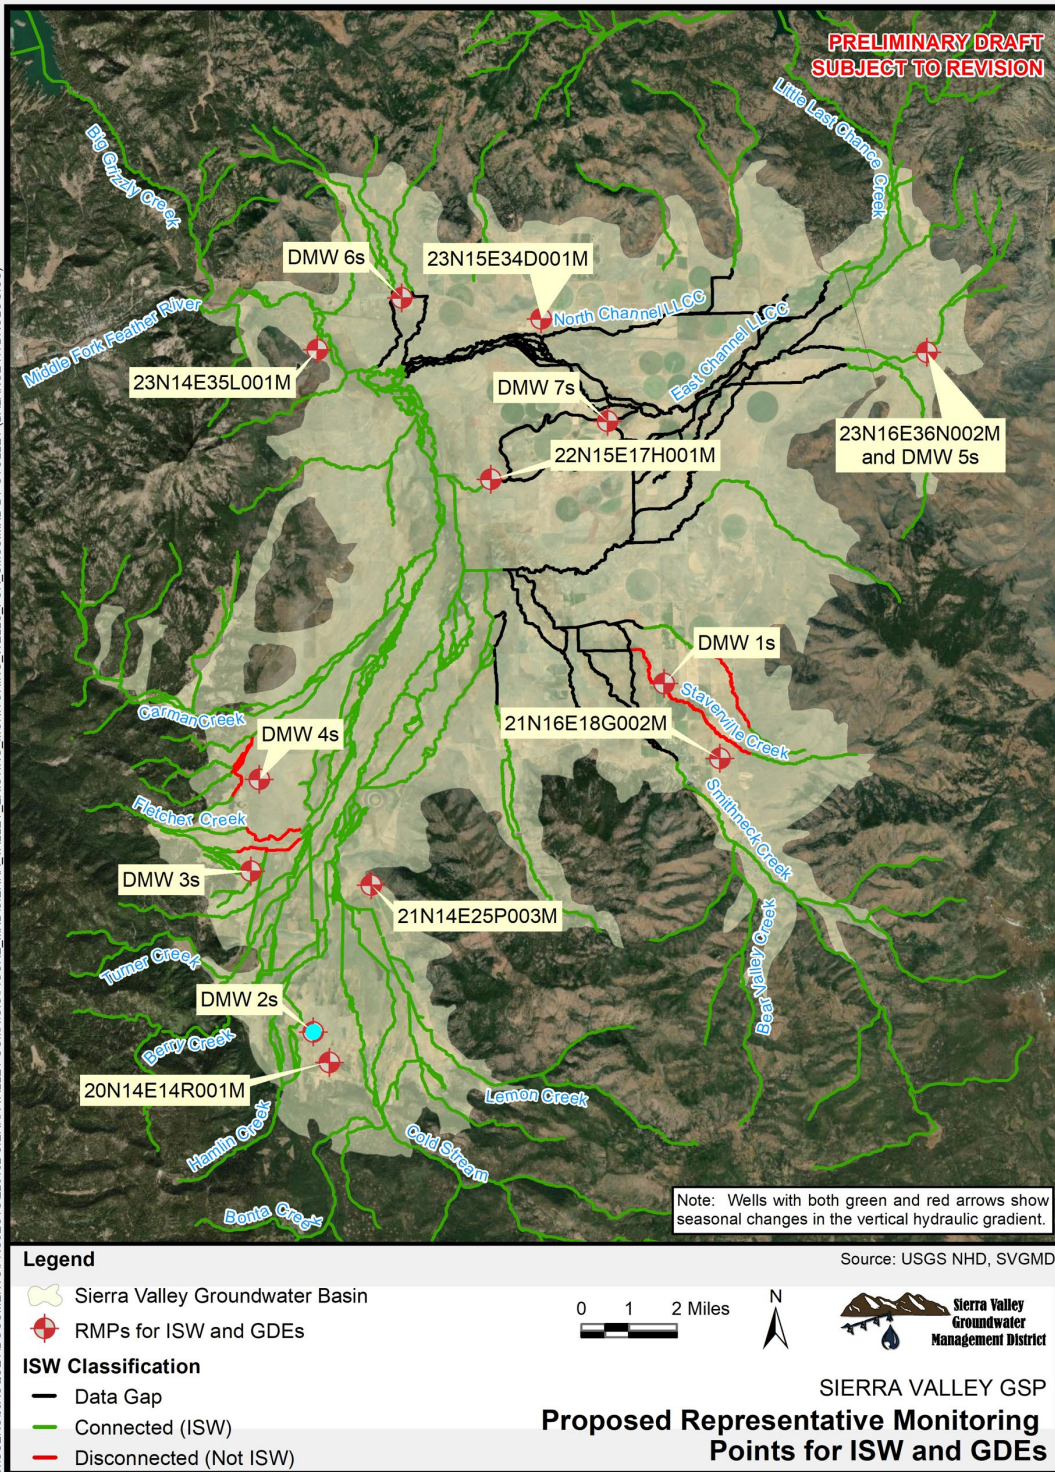

448 Groundwater elevations may be used as a proxy for a sustainability indicator if there is a
 449 significant correlation between the sustainability indicator in question and groundwater
 450 elevations. Groundwater elevations directly control the stream-aquifer hydraulic gradient, and
 451 thus, the magnitude of ISW depletion. In the absence of high-confidence estimates of
 452 streamflow depletion, but reasonable groundwater level data, we set conservative MTs near
 453 ISW and GDEs that would maintain groundwater elevations above historically observed lows
 454 and thus reduce the risk that hydraulic gradients between surface and groundwater do not
 455 reverse or steepen. In other words, these conservative groundwater level MTs protect ISW from
 456 experiencing depletion in excess of historically observed values by controlling stream-aquifer
 457 hydraulic gradients.

458 To protect priority species that rely on ISW, MTs are set for existing monitoring wells that are
 459 located nearest to sensitive GDEs and ISW. RMPs associated with ISW or GDEs that support
 460 priority species are assigned a groundwater level MT equal to the lowest reading since
 461 January 2000 (**Figure 3.3.3-1, Figure 3.3.3-2, and Table 3.3.3-1**). All ISW RMPs except 37 and
 462 364 are contained in the groundwater level RMP network.

463 **Table 3.3.3-1. MTs and MOs for select RMPs associated with GDEs and ISW**

 467 **for data gaps (orange), disconnected reaches (red), and ISW (blue).**

468 **3.3.3.4.2 Triggers**

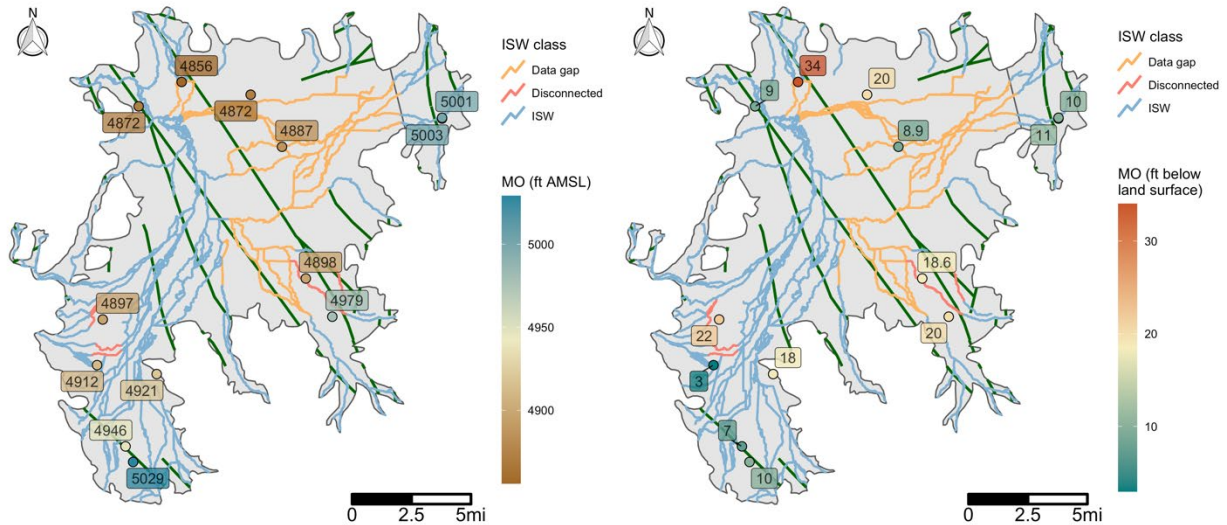

469 The trigger for management action will be if the water level falls within...

470 **3.3.3.5 Measurable Objectives**

471 Measurable Objectives for the depletion of ISW are consistent with those for Groundwater
 472 Elevation. Thus, ISW MOs are based on the mean of the current (2015 to 2021) groundwater
 473 conditions in the basin at each RMPs (Figure 3.3.3-3 and Table 3.3.3-1).

474
475
476

Figure 3.3.3-3. MOs at ISW RMPs in terms of elevation above mean sea level (left) and depth below land surface (right). Faults are shown as dark green lines. ISW classification (Chapter 2) is shown for data gaps (orange), disconnected reaches (red), and ISW (blue).

477 **3.3.3.6 Path to Achieve Measurable Objectives**

478 The GSA will support achievement of the measurable objectives by monitoring groundwater
479 levels and surface water elevations at RMPs and coordinating with agencies and stakeholders
480 within the Basin to implement projects and management actions (PMAs). The GSA will review
481 and analyze groundwater level data to evaluate any changes in groundwater levels resulting
482 from groundwater pumping or recharge projects in the Basin. Using monitoring data collected as
483 part of GSP implementation, the GSA will develop information (e.g., hydrographs) to
484 demonstrate that projects and management actions are operating to maintain or improve
485 groundwater level conditions in the Basin and to avoid unreasonable groundwater levels.
486 Should groundwater levels drop to a **trigger** or minimum threshold, the GSAs will implement
487 measures to address this occurrence.

488 **3.3.3.7 Interim Milestones**

489 **Interim milestones are consistent with those set for groundwater level SMC (Section 3.3.1.6.1).**

490 **3.3.4 Degraded Groundwater Quality**

491 Groundwater quality in the SV Subbasin is generally good and well-suited for the municipal,
492 domestic, agricultural, and other existing and potential beneficial uses designated for
493 groundwater in the Water Quality Control Plan for the Sacramento River Basin and the
494 San Joaquin River Basin (Basin Plan). Existing groundwater quality concerns within the SV
495 Subbasin are identified in **Section 2.2.2.4**, and a detailed water quality assessment is included
496 in **Appendix ## of Chapter 2**. Based on the water quality assessment, constituents of concern in
497 the SV Subbasin were deemed to include nitrate, total dissolved solids (TDS), arsenic, boron,
498 pH, iron, manganese, and MTBE. SMCs are defined for two constituents: nitrate and TDS.

499 Arsenic, boron, pH, iron, and manganese are impacted significantly by natural processes and
500 local geological conditions that are not controllable by the GSAs through groundwater
501 management processes. Therefore, SMCs are not defined for these constituents. Additionally,
502 as detailed in **Section 2.2.2.4**, MTBE have diminished substantially over the last 10 years: from
503 2016 to 2020 no exceedances of the 5 µg/L SMCL occurred and the highest concentration
504 measured during this period was 0.7 µg/L), and therefore no SMC is defined for this constituent,
505 and moreover it is associated with contaminated sites that have dedicated monitoring and
506 cleanup and is not likely a risk for future contamination.

507 In addition to conducting monitoring for the constituents with SMCs (nitrate and TDS), the GSA
508 will monitor arsenic, boron, and pH to track any potential mobilization of elevated concentrations
509 or exceedances of the Maximum Contaminant Levels (MCLs, provided in **Section 2.2.2.4**,
510 **Table 2.2.2-1**). As the regional groundwater flow model becomes available, additional attention
511 will be paid to how groundwater pumping may mobilize contaminant plumes.

512 Water quality degradation is typically associated with increasing constituent concentration, thus
513 the GSAs have decided not to use the term “minimum threshold” in the context of water quality,
514 but rather, “maximum threshold”.

515 **3.3.4.1 Undesirable Results**

516 An undesirable result under SGMA is defined as an impact that is determined to be significant
517 and unreasonable, as previously defined in **Section 3.1**. Significant and unreasonable
518 degradation of groundwater quality is the degradation of water quality that would impair
519 beneficial uses of groundwater within the SV Subbasin or result in the failure to comply with
520 groundwater regulatory thresholds including state and federal drinking water standards and
521 Basin Plan water quality objectives. While others may be identified, undesirable results to
522 groundwater quality that are currently of primary concern include:

- 523 • adverse groundwater quality impacts to safe drinking water,
- 524 • adverse groundwater quality impacts to irrigation water use,
- 525 • the spread of degraded water quality through old or abandoned wells; and,
- 526 • the spread of degraded groundwater quality.

527 Based on the State’s 1968 antidegradation policy², water quality degradation inconsistent with
528 the provisions of this policy is degradation determined to be significant and unreasonable.
529 Furthermore, the violation of water quality objectives is significant and unreasonable under the
530 State’s antidegradation policy. The Central Valley Regional Water Quality Control Board
531 (Regional Board) and the State Water Board are the two entities that determine if degradation is
532 inconsistent with Resolution No. 68-16.

533 Federal and state water quality standards, water quality objectives defined in the Basin Plan,
534 and the management of known and suspected contaminated sites within the Subbasin will
535 continue to be the jurisdictional responsibility of the relevant regulatory agencies. The role of the
536 GSAs is to provide additional local oversight of groundwater quality, collaborate with appropriate
537 parties to implement water quality projects and actions, and to evaluate and monitor, as needed,
538 water quality effects of projects and actions implemented to meet the requirements of other
539 SMCs.

² State Water Resources Control Board. “Resolution No. 68-16: Statement of Policy with Respect to Maintaining High Quality of Waters in California”, California, October 28, 1968.

540 Sustainable management of groundwater quality includes maintenance of water quality within
541 regulatory and programmatic limits while executing GSP projects and actions. To achieve this
542 goal, the GSAs will coordinate with the regulatory agencies that are currently authorized to
543 maintain and improve groundwater quality within the Subbasin. This includes informing the
544 Regional Board of any issues that arise and working with the Regional Board to address
545 potential problems. All future projects and management actions implemented by the GSAs will
546 be evaluated and designed to avoid causing undesirable groundwater quality outcomes.
547 Monitoring should be included as part of the applicable project or management action to allow
548 evaluation of any impacts. Historic and current groundwater quality monitoring data and
549 reporting efforts have been used to document baseline groundwater quality conditions in the
550 basin. These conditions provide a baseline to compare with future groundwater quality and
551 identify any changes observed due to GSP implementation.

552 In addition to supporting agricultural and domestic water supply beneficial uses, groundwater
553 also supports GDEs and instream environmental resources. These beneficial uses, among
554 others, are protected in part by the Regional Board through the water quality objectives adopted
555 in the Basin Plan. The constituents of concern in the Subbasin, and their associated regulatory
556 thresholds, are listed in **Section 2.2.2.4**.

557 *3.3.4.1.1 Potential Causes of Undesirable Results*

558 Future monitored activities or conditions with potential to affect water quality may include
559 significant changes in location and magnitude of groundwater pumping or changes to planned
560 and incidental groundwater recharge mechanisms sufficient to change the flow and transport of
561 subsurface contaminants. Altering the location or rate of groundwater pumping could change
562 the direction of groundwater flow which may redirect existing contaminant plumes, or plumes
563 that may develop in the future, thus potentially compromising ongoing remediation efforts.
564 Similarly, recharge activities could alter hydraulic gradients which could result in the downward
565 movement of contaminants into groundwater or move existing groundwater contaminant plumes
566 towards supply wells.

567 Sources and activities that may lead to undesirable groundwater quality include industrial
568 contamination, pesticides, sewage, animal waste, and other wastewaters, and natural causes.
569 Fertilizers and other agricultural activities can elevate concentrations of constituents such as
570 nitrate and TDS. Wastewater, such as sewage from septic tanks and animal waste, can also
571 elevate nitrate and TDS concentrations. Natural causes, such as local volcanic geology and
572 soils), can elevate concentrations of arsenic, boron, iron, manganese, pH, and TDS. The GSAs
573 cannot control and are not responsible for natural causes of groundwater contamination but are
574 responsible for how project and management actions may impact groundwater quality (e.g.,
575 through mobilization of naturally occurring contaminants).

576 Groundwater quality degradation associated with known sources will be primarily managed by
577 the Regional Board which is the entity currently overseeing such sites. In the SV Subbasin,
578 existing contaminant sites are currently being managed, and though additional degradation is
579 not anticipated from known sources, new sites may cause undesirable results due to
580 constituents that, depending on the contents, may include petroleum hydrocarbons, solvents, or
581 other contaminants. The Subbasin is not currently categorized as a priority subbasin under the
582 CV-SALTS program managed by the Regional Board.

583 Agricultural activities in the SV Subbasin primarily include pasture, grain and hay, and alfalfa.
584 Alfalfa and pasture production have low risk for fertilizer-associated nitrate leaching into the
585 groundwater (Harter et al., 2017). Grain production is rotated with alfalfa production, usually for
586 one year, after which alfalfa is replanted. Grain production also does not pose a significant

587 nitrate-leaching risk. Animal farming, a common source of nitrate pollution, is present but not at
588 stocking densities of major concern. Changes or additions to land uses may require a re-
589 examination of groundwater contamination risk.

590 **3.3.4.2 Effects on Beneficial Uses and Users**

591 Potential adverse water quality impacts to the beneficial uses of groundwater in the Subbasin
592 are identified by elevated or increasing concentrations of constituents of concern, and the
593 potential local or regional effects that degraded water quality can have on such beneficial uses.
594 Potential adverse water quality impacts to the beneficial uses of groundwater in the Subbasin
595 are identified by elevated or increasing concentrations of constituents of concern, and the
596 potential local or regional effects that degraded water quality can have on such beneficial uses.

597 The potential impact of poor groundwater quality on major classes of beneficial users is now
598 discussed:

- 599 • **Municipal Drinking Water Users:** Under California law, agencies that provide drinking
600 water are required to routinely sample groundwater wells and compare the results to
601 state and federal drinking water standards for individual constituents. Groundwater
602 quality that does not meet state drinking water standards may render the water unusable
603 or require additional treatment, carried out by the agency. Impacted municipal supply
604 wells may potentially be taken offline until a solution is found, depending on the
605 constituents detected and the configuration of the municipal system in question. This
606 reduces the reliability of the overall water supply system during the rehabilitation period.
- 607 • **Rural and/or Agricultural Residential Drinking Water Users:** Residential structures
608 not located within the service areas of a local municipal water agency or private water
609 supplier will typically obtain water supply from private domestic groundwater wells.
610 Unless on the number of connections serviced by the well is sufficiently large, the well
611 will not have a regulatory groundwater quality testing requirement. Thus, groundwater
612 quality at such wells may be unknown unless the landowner has initiated testing and
613 shared the data with other entities. Degraded water quality in such wells can lead to rural
614 residential groundwater use that does not meet potable water standards and results in
615 the need for installation of new or modified domestic wells and/or well-head treatment
616 that provides acceptable quality groundwater.
- 617 • **Agricultural Users:** Irrigation water quality bears importantly on crop production and
618 has a variable impact on agriculture due to different crop sensitivities. Impacts from poor
619 water quality (e.g., elevated salinity) may include declines in crop yields, crop damage,
620 and alterations to the crops that can be grown in the area (e.g., depending on salt
621 tolerance).
- 622 • **Environmental Uses:** In gaining streams, poor quality groundwater may result in
623 contaminant migration which may impact groundwater dependent ecosystems or
624 instream environments, and the species therein.

625 **3.3.4.3 Relationship to Other Sustainability Indicators**

626 Groundwater quality does not typically influence other sustainability indicators, which are more
627 influenced by groundwater *quantity*. However, in some circumstances, groundwater quality can
628 be affected by changes in groundwater levels and reductions in groundwater storage, because
629 activities which alter basin groundwater flow patterns can also mobilize subsurface
630 contaminants.

- 631
- 632
- 633
- 634
- 635
- 636
- 637
- 638
- **Groundwater Levels:** In some instances, declining groundwater levels can potentially lead to increased concentrations of constituents of concern in groundwater and may alter the existing hydraulic gradient, which can result in the movement of contaminated groundwater plumes. Changes in groundwater levels may also mobilize some contaminants that may be present in unsaturated soils. In such cases, the MTs established for groundwater quality may influence groundwater level minimum thresholds by limiting the location or number of projects (e.g., groundwater recharge), to avoid degradation of groundwater quality.
 - **Groundwater Storage:** The groundwater quality MTs will not cause groundwater pumping to exceed the basin sustainability yield³ and therefore will not cause exceedances of the groundwater storage minimum thresholds.
 - **Depletion of Interconnected Surface Waters:** The groundwater quality MT does not promote additional pumping or lower groundwater levels near interconnected surface waters. The groundwater quality MT does not negatively affect interconnected surface waters.
 - **Seawater Intrusion:** This sustainability indicator is not applicable in the SV Subbasin.
 - **Subsidence:** The groundwater quality MT does not promote additional pumping or lower groundwater levels and therefore does not interfere with subsidence minimum thresholds. In some cases, and depending on the basin's subsurface composition, extreme land subsidence (e.g., similar to rates in California's Central Valley) can lead to elevated arsenic concentrations (Smith et al., 2018), although this effect is not expected in the SV Subbasin because the basin pumping is moderate and subsurface arsenic-rich clays are not abundant.

657

658

659

660

661

The two constituents of concern (nitrate and TDS) for which SMCs were considered were specifically selected due to stakeholder input and prevalence as a groundwater contaminant in California. Constituents of concern were identified using current and historical groundwater quality data; this list may be reevaluated during future GSP updates. In establishing MTs for groundwater quality, the following information was considered:

- 661
- 662
- 663
- 664
- 665
- 666
- 667
- 668
- 669
- 670
- 671
- Feedback about water quality concerns from stakeholders.
 - An assessment of available historical and current groundwater quality data from wells in the Subbasin.
 - An assessment of historical compliance with federal and state drinking water quality standards and water quality objectives.
 - An assessment of trends in groundwater quality at selected wells with adequate data to perform the assessment.
 - Information regarding sources, control options and regulatory jurisdiction pertaining to constituents of concern.
 - Input from stakeholders resulting from the consideration of the above information in the form of recommendations regarding MTs and associated management actions.

³ This will be confirmed by the integrated hydrologic model and updated as needed.

672 The historical and current groundwater quality data used to establish groundwater quality MTs
673 are discussed in **Section 2.2.2.4**. Based on a review of these data, applicable water quality
674 regulations, Subbasin water quality needs, and information from stakeholders, the GSAs
675 determined that state drinking water standards (MCLs and Water Quality Objectives) are
676 appropriate to define MTs for groundwater quality (**Table 3.3.4-1**). Hence, MTs for groundwater
677 quality are set to the Title 22 primary MCL for nitrate (10 mg/L), and the Title 22 secondary MCL
678 for TDS (500 mg/L). These MTs protect and maintain groundwater quality for existing and
679 potential beneficial uses and users.

680 New constituents of concern may be added with changing conditions and as new information
681 becomes available.

682 **3.3.4.5 Maximum Thresholds**

683 MTs for groundwater quality were defined in consultation with the GSA advisory committee and
684 stakeholders, and consider of historical and present day groundwater quality data, beneficial
685 uses of groundwater in the SV Subbasin, and existing regulations (**Section 2.2.2.4**). Existing
686 regulations include water quality objectives in the Basin Plan, Title 22 Primary MCLs, and
687 Secondary MCLs. As a result of this process, SMCs were developed for two constituents of
688 concern in the Subbasin: nitrate, and TDS.

689 Although MTBE is identified as a potential constituent of concern in **Section 2.2.2.4**, no SMC is
690 defined for this constituent as it is associated with contaminated sites that have dedicated
691 monitoring and cleanup and is not likely a risk for future contamination. Recent MTBE data
692 (2016-2020) resulted in no exceedances of the 5 µg/L SMCL; the highest concentration
693 measured during this period was 0.7 µg/L. Arsenic, boron, iron, manganese, and pH were not
694 assigned SMCs because they are naturally occurring, although they will be monitored as part of
695 the GSP and Basin Plan.

696 The selected MTs for the concentration of TDS and nitrate, and their associated regulatory
697 thresholds, are listed in **Table 3.3.4-1**. Importantly, **Undesirable Results for groundwater
698 quality occur when any well in the RMP exceeds MTs for nitrate or TDS at a number of
699 wells greater than the number of wells that show exceedances at the time of writing
700 (2021-09-01)**. Exceedances already exist at some RMPs and these exceedances will likely
701 continue into the future. The MT for the number of allowed exceedance wells is therefore equal
702 to the current number of wells with exceedances (none for nitrate, and three for TDS). The
703 identification of Undesirable Results is therefore based on the *number* of wells to have
704 exceedances for each nitrate and TDS, not necessarily the *same* wells. As denoted in
705 **Table 3.3.4-1** and **Table 3.3.4-2**, there are no wells with exceedances of the nitrate MT, and
706 three wells with exceedances of the TDS MT. For example, an MTs for nitrate and TDS are zero
707 and three wells respectively, and an Undesirable Result would occur if one well showed a
708 nitrate exceedance, or if four wells showed a TDS exceedance.

709 An average of water quality samples will be used for wells that are measured more than once a
710 year. As MTs are currently based on only existing wells, the water quality monitoring network
711 will be reassessed every five years to identify any new wells that should be added to the
712 network. If future water quality data collected from the network results in exceedances of MCLs
713 and SMCLs of additional constituents, MTs and MOs will be developed for these additional
714 constituents.

715 As described in **Section 3.4.1.3**, the groundwater quality monitoring network is not currently
716 finalized for this GSP due to data gaps in well construction information, and inadequate spatial
717 coverage. However, an initial analysis of water quality data for the proposed network was

718 conducted to establish the interim MTs and MOs that will be updated once the data gaps are
719 filled and a more complete assessment of this monitoring network can be established.

720 **3.3.4.5.1 Triggers**

721 The GSAs will use concentrations of the identified constituents of concern (nitrate and TDS)
722 below the MT as triggers for action to proactively avoid the occurrence of undesirable results.
723 Triggers are warning concentrations defined to indicate that groundwater quality degradation
724 may be occurring, and that additional attention or action may be needed to avoid an increase to
725 the MT. If the triggers are exceeded, the GSAs will conduct an investigation and may use
726 management actions. As listed in **Table 3.3.4-1** the trigger value for TDS is 55% of the Title 22
727 Secondary MCL (275 mg/L), while the trigger values for nitrate are half and 90% of the Title 22
728 MCL (5 mg/L and 9 mg/L, respectively).

729 **3.3.4.5.2 Method for Quantitative Measurement of Maximum Thresholds**

730 Groundwater quality will be measured in representative monitoring wells as discussed in
731 **Section 3.4.1.3**. Statistical evaluation of groundwater quality data obtained from the monitoring
732 network will be performed. The MTs for constituents of concern are shown in **Table 3.3.4-1** and

733 Figure 3.3.4-1, which show “rulers” for each of the two identified constituents of concern, with
734 the associated MTs, MOs, and triggers. MOs are detailed in the following subsection.

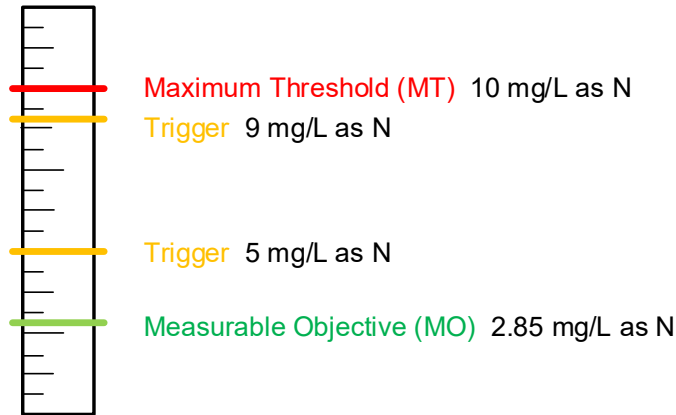

735 **Table 3.3.4-1. Constituents of Concern and the Associated Maximum Thresholds and Triggers**

| Constituent | Maximum Threshold (MT) | Regulatory Threshold | Maximum Threshold, Number of Wells Exceeding MT Concentration |
|------------------------------|------------------------|-------------------------------------|---------------------------------------------------------------|
| Nitrate as Nitrogen | 5 mg/L, trigger only | 10 mg/L (Primary MCL – Title 22) | 0 |
| | 9 mg/L, trigger only | | |
| | 10 mg/L, MT | | |
| Total Dissolved Solids (TDS) | 275 mg/L, trigger only | 500 mg/L (Secondary MCL – Title 22) | 3 |
| | 500 mg/L, MT | | |

736

Nitrate as Nitrogen

Total Dissolved Solids

739 **3.3.4.6 Measurable Objectives**

740 MOs are defined under SGMA as described previously in **Section 3.1** and represent the desired
741 condition to be achieved to satisfy each Sustainability Indicator. Within the Subbasin, the MOs
742 for water quality are established to provide an indication of desired water quality at levels that
743 are sufficiently protective of beneficial uses and users. MOs differ from triggers in that they
744 define concentrations that will allow the Subbasin to achieve its sustainability goal within
745 20 years of Plan implementation. For nitrate and TDS, MOs are defined on a well-specific basis,
746 with consideration for historical water quality data.

747 **3.3.4.6.1 Description of Measurable Objectives**

748 The MOs for wells within the water quality monitoring network where concentrations have
749 historically been below the MTs for water quality, are the highest measured concentrations
750 during the period 1990 to July 2020. For wells where the concentrations have historically
751 exceeded or equaled 90% of the MT, the MO is instead 90% of the MT. For newly installed or
752 newly monitored wells, the MO will be preliminarily set to the first measured concentration until
753 more data is available to set more informed SMC. As with wells that have historically been

754 monitored, if this concentration exceeds or equals 90% of the MT, the MO will instead be 90%
755 of the MT. In instances where the highest measured concentration of nitrate is a non-detect
756 value, the MO is defined as 0.05 mg/L.

757 Specifically, for nitrate and TDS, the MO for the monitoring network is for individual wells not to
758 exceed the MO for two consecutive years. The MOs for nitrate and TDS at proposed
759 representative monitoring points within the SV Subbasin are listed in **Table 3.3.4-2**.

760 **3.3.4.7 Path to Achieve Measurable Objectives**

761 The GSAs will support the protection of groundwater quality by monitoring groundwater quality
762 conditions and coordinating with the relevant regulatory agencies that work to maintain
763 groundwater quality in the Subbasin. All future projects and management actions will be
764 implemented by the GSAs with the intent to comply with state and federal water quality
765 standards and Basin Plan water quality objectives and will be designed to maintain groundwater
766 quality for all uses and users and avoid causing unreasonable groundwater quality degradation.
767 The GSAs will review and analyze groundwater monitoring data as part of GSP implementation
768 to evaluate any changes in groundwater quality resulting from groundwater pumping or
769 recharge projects (anthropogenic recharge) in the Subbasin. The need for additional studies on
770 groundwater quality will be assessed throughout GSP implementation. The GSAs may identify
771 data gaps, seek funding, and help to implement additional studies.

772 Using monitoring data collected as part of project implementation, the GSAs will develop
773 information (e.g., time-series plots of water quality constituents) to demonstrate that projects
774 and management actions are operating to maintain or improve groundwater quality conditions in
775 the Subbasin and to avoid unreasonable groundwater quality degradation. Should the
776 concentration of a constituent of concern increase above its MO or trigger value as the result of
777 GSAs project implementation, the GSAs will implement measures to address this occurrence.
778 This process is illustrated in **Figure 3.3.4-2**, and depicts the high-level decision making that
779 goes into developing SMCs, monitoring to determine if criteria are met, and actions to be taken
780 based on monitoring results

781 If a degraded water quality trigger is exceeded, the GSAs will investigate the cause and source
782 and implement management actions as appropriate. Where the cause is known, projects and
783 management actions along with stakeholder education and outreach will be implemented.
784 Examples of possible GSAs actions include notification and outreach to impacted stakeholders,
785 alternative placement of groundwater recharge projects, and coordination with the appropriate
786 water quality regulation agency. Projects and management actions are presented in further
787 detail in **Chapter 4**.

788 Exceedances of nitrate, and TDS will be referred to the Regional Board. Where the cause of an
789 exceedance is unknown, the GSAs may choose to conduct additional or more frequent
790 monitoring.

791
792

Table 3.3.4-2. Potential Groundwater Quality Monitoring Wells and Associated Measurable Objectives

| Well Description | Well ID | Measurable Objectives (mg/L) | | Notes |
|---------------------------------------------------|---------------|------------------------------|--------------------|----------------------------------------------------------------------------------------------|
| | | Nitrate as Nitrogen | TDS | |

^(b) TDS measurable objective set to 90% of maximum threshold due to historical exceedance of this value

N/A = the well has not been identified, and therefore historical monitoring data is not yet available

796 3.3.4.7.1 Interim Milestones

797 As existing groundwater quality data indicate that groundwater in the Subbasin generally meets
 798 applicable state and federal water quality standards for nitrate and TDS, the objective is to
 799 maintain existing groundwater quality. Interim milestones are therefore set to maintain
 800 groundwater quality equivalent to the MOs established for nitrate and TDS, with the goal of
 801 maintaining water quality within the historical range of observed values.

802 **Figure 3.3.4-2. Degraded water quality sustainable management criteria flow chart**

803 The flow chart depicts the high-level decision making that goes into developing SMCs,
 804 monitoring to determine if criteria are met, and actions to be taken based on monitoring results.

805 **3.3.5 Land Subsidence**

806 Sierra Valley has experienced land subsidence in the past and some land subsidence continues
 807 into the present day. Subsidence has occurred in varying areas in Sierra Valley over time, and
 808 has overlapped with areas of significant groundwater pumping. The Sierra Valley subsurface
 809 geology is typical of Californian mountain valleys, and predominantly composed of eroded,
 810 alluvial, sedimentary deposits (e.g., clay, silt, sand, and gravel). The clay deposits are

811 particularly susceptible to inelastic compression resulting in land subsidence when significant
812 levels of drawdown have occurred.

813 The first recorded account of subsidence in Sierra Valley was by the California Department of
814 Water Resources (DWR; 1983). DWR (1983) and Plumas County Road Department surveys
815 reported localized groundwater level decline and inelastic subsidence of about 1 to over 2 feet
816 between 1960 and 1983 (i.e., an effective annual subsidence rate of about 0.05 to 0.1+
817 feet/year). Subsidence from 1983 to 2012 is unknown – records during this time are not
818 available. During the severe 2012 to 2016 drought, the California Department of Transportation
819 (CalTrans) surveyed areas of heavy groundwater pumping and water level drawdown
820 corresponded to an estimated subsidence of 0.3 to 1.9 feet (i.e., approximately 0.08 to
821 0.48 feet/year). These results agree with another estimate made between 2015 and 2016:
822 satellite-based Interferometric Synthetic Aperture Radar (InSAR) data from NASA JPL
823 suggested subsidence in the northeastern Sierra Valley up to 0.5 feet/year (insert reference).
824 From March of 2015 to November 2019, the same NASA JPL InSAR data suggests up to
825 1.2 feet of subsidence (i.e., about 0.3 feet/year). During the same period, DWR/TRE by Altamira
826 (2020), estimated 0.15 ± 0.1 feet/year of subsidence, which is about half the land subsidence
827 estimated by NASA JPL.

828 The above paragraph is less than ideal. Insert table of each of these land subsidence studies
829 with columns “study”, “date range”, “average annual subsidence”.

830 **3.3.5.1 Undesirable Results (Reg. § 354.26)**

831 An undesirable result occurs when subsidence substantially interferes with beneficial uses of
832 groundwater and surface land uses. Subsidence occurs when excessive groundwater pumping
833 dewateres typically fine-grained sediments (e.g., clays and silts) causing them to compact, either
834 temporarily (elastic subsidence) or permanently (inelastic subsidence). Clay and silt sediments
835 are only moderately present in the eastern side of the Subbasin. Locations notably susceptible
836 to detrimental impacts from subsidence are locations where differential subsidence occurs
837 (subsidence transitions from little to no subsidence to moderate to heavy subsidence in a short
838 lateral distance). Differential subsidence prone areas include zones along faults where
839 drawdown effects are constrained on side of the fault, and zones of rapid transition from fine to
840 coarse grained sediments, such as near alluvial fan transitions to valley floor sediments.
841 Specific examples of undesirable results include substantial interference with land use, and
842 significant damage to critical infrastructure, such as building foundations, roadways, other
843 infrastructure elements, canals, pipes, and water conveyance infrastructure.

844 **3.3.5.2 Effects on Beneficial Uses and Users**

845 Potential effects on the beneficial uses and users of groundwater, on land uses and property
846 interests, and other potential effects that may occur or are occurring from undesirable results
847 could be:

- 848 • Financial impacts to all groundwater users and well owners for mitigation costs and
849 supplemental supplies (including de minimis groundwater users and members of
850 disadvantaged communities)
- 851 • Impacts to shallow wells (<100 ft deep) due to potentially degraded water quality,
852 requiring well treatment or abandonment
- 853 • Land subsidence causing impacts to infrastructure, private structures, and/or land uses
- 854 • Irreversible losses to aquifer storage permeability and storage capacity
- 855 • Damage to wells (subsidence can cause wellhead damage or casing failure)

856 **3.3.5.3 Relationship to Other Sustainability Indicators**

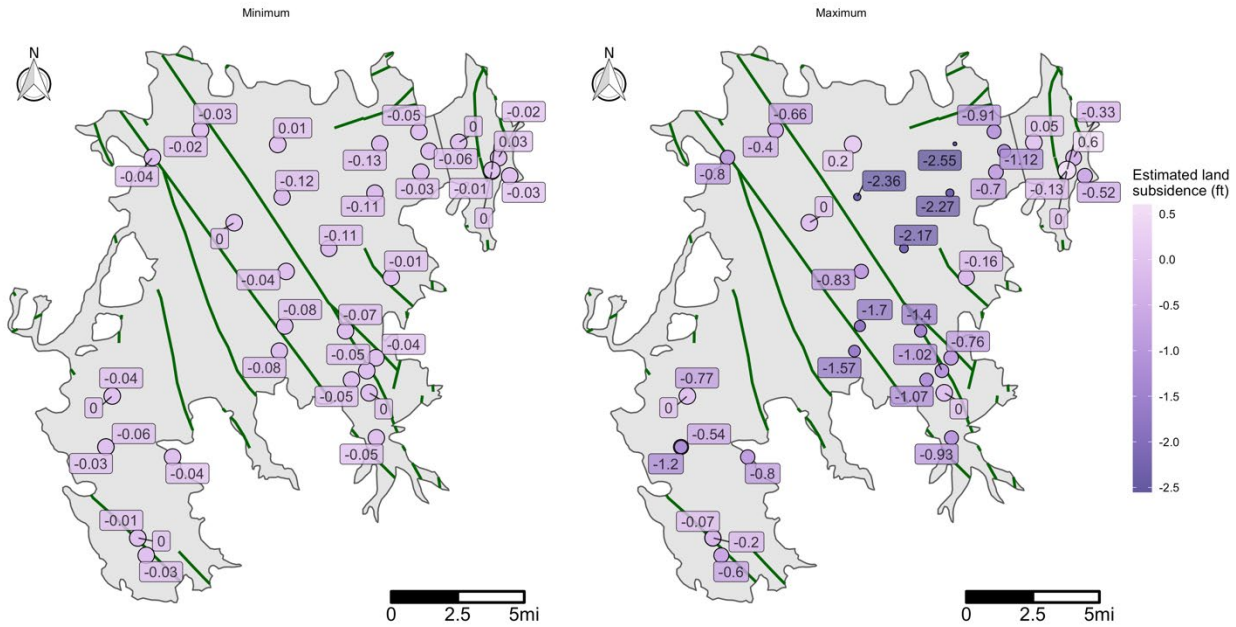

857 By mainly managing groundwater pumping and avoiding the undesirable result of chronic
858 lowering of groundwater levels (**Section 3.3.1**), the possibility of land subsidence will be
859 mitigated. Mitigating land subsidence through sustainably managed groundwater levels in the
860 Subbasin will also mitigate impacts to related undesirable groundwater storage declines.

861 **3.3.5.4 Information and Methodology Used to Establish Minimum Thresholds and**
862 **Measurable Objectives (Reg. § 354.30)**

863 Although InSAR satellite-based measures of land subsidence are available for the SV Subbasin,
864 these data are relatively recent, do not show long-term trends, and indicate total subsidence
865 which can represent a combination of elastic subsidence (reversible subsidence) and inelastic
866 subsidence (irreversible subsidence). Furthermore, ground-based data do not conclusively
867 determine the extent of long-term, inelastic subsidence. As such, adequate, Subbasin-specific
868 information correlating the detailed, long-term connection between land subsidence and
869 groundwater levels is lacking. However, Poland and Davis (1969) estimated the land
870 subsidence to groundwater level decline ratio is approximately 0.01 to 0.2 feet of subsidence
871 per foot of groundwater level decline. Potential land subsidence under specified MTs thus
872 ranges from 0 to 2.55 feet depending on the location in the basin as shown in **Figure 3.3.5-1**.
873 Ranges are calculated assuming 0.001 to 0.2 feet of subsidence per foot of groundwater level
874 decline, consistent with Poland and Davis (1969). Larger distance between recent historic lows
875 (around fall 2015) and groundwater level MTs leads to increased estimated land subsidence. At
876 this time, significant and unreasonable impacts to beneficial uses and users are not anticipated
877 under these land subsidence estimates. Substantial uncertainty is present in these estimates
878 thus they should be cautiously interpreted. Importantly, due to the relatively long-time scales on
879 which land subsidence occurs, land subsidence should be monitored, used to validate the work
880 of Poland and Davis (1969), and adaptively managed. Impacts to roads and wells are of
881 particular concern in the basin and will also be monitored.

882
883

Figure 3.3.5-1: Minimum (left) and maximum (right) range of land subsidence implied by the change in groundwater level between recent historic lows (fall 2015) and groundwater level MTs.

884 Currently, groundwater levels offer the only long-term measure that can serve as a proxy for
 885 land subsidence for the Subbasin, by using the correlations established by Poland and Davis.
 886 For the first five years, the GSP will use groundwater elevation proxy for land subsidence.
 887 Within the first five years of plan implementation, effort will be made to demonstrate more robust
 888 correlations with different subsidence data types, and an adaptive, composite methodology for
 889 assessing land subsidence will be developed to supplement the groundwater level proxy. This
 890 will incorporate groundwater levels, ground-based elevation surveys, and satellite-based InSAR
 891 data.

892 **3.3.5.5 Minimum Thresholds (Reg. § 354.28)**

893 The Sierra Valley basin lacks adequate information detailing aquifer lithology, aquitard units,
 894 and long-term land-subsidence trends. Satellite-based InSAR data are useful for assessing total
 895 land subsidence, these data have only been processed for 2015-2019. It is assumed that
 896 InSAR data will continue to be collected from agencies operating satellites during the
 897 implementation period by DWR. These measurements will be coupled with groundwater
 898 elevation and ground-based survey data to inform adaptive management and the development
 899 of more refined MTs in the next 5 year plan update.

900 23 CCR § 354.28(d) states: “An Agency may establish a representative MT for groundwater
 901 elevation to serve as the value for multiple sustainability indicators, where the Agency can
 902 demonstrate that the representative value is a reasonable proxy for multiple individual MTs as
 903 supported by adequate evidence.”

904 This GSP adopts groundwater level as a proxy for changes in land subsidence, using evidence
 905 of a linear and physical relationship between land subsidence and groundwater level change
 906 documented by Poland and Davis (1969) and detailed in **Section 3.3.5.4**. Thus, the MT for land

907 subsidence for this GSP is the same as the MT for groundwater levels as detailed in
908 **Section 3.3.1.4.**

909 There are currently no other state, federal, or local standards that relate to this sustainability
910 indicator in the Subbasin. Management areas are not planned for this GSP at this time. Land
911 subsidence MTs apply to the entire subbasin area.

912 **3.3.5.6 Measurable Objectives**

913 Using groundwater level as a proxy, the MOs and IMs for land subsidence for this GSP are
914 identical to groundwater level MOs and IMs, as detailed in **Section 3.3.1.4.** Protecting against
915 chronic lowering of groundwater levels will directly protect against land subsidence.

916 Management areas are not planned for this GSP at this time. The MOs and associated interim
917 milestones apply to the entire subbasin area.

918 **3.3.5.7 Path to Achieve Measurable Objectives**

919 GSAs will continue to monitor groundwater elevation and combine these data with InSAR and
920 ground-based elevation surveys to measure progress towards MOs and to improve
921 understanding of land subsidence in the basin. GSAs will coordinate with the relevant
922 stakeholders to determine impacts to beneficial users and uses that may be impacted by land
923 subsidence and take necessary actions to adaptively manage groundwater pumping and avoid
924 significant and unreasonable impacts. Beyond these actions, the GSAs will approach
925 groundwater level management as described in **Section 3.3.1.6.**

926 **3.4 Monitoring Networks (Reg. § 354.26)**

927 Monitoring is fundamental to measure progress towards Plan management goals. The
928 monitoring networks described in this subsection support data collection to monitor the SV
929 Subbasin's sustainability indicators which include the lowering of groundwater levels, reduction
930 of groundwater storage, depletion of interconnected surface water, degradation of water quality,
931 and land subsidence. Monitoring data will be used to track spatial and temporal changes in
932 groundwater conditions that may result from projects and actions that are part of GSP
933 implementation.

934 Per 23 CCR § 354.34, monitoring networks should be designed to:

- 935 • Demonstrate progress towards achieving MOs described in the Plan,
- 936 • Monitor impacts to the beneficial uses or users of groundwater,
- 937 • Monitor changes in groundwater conditions relative to MOs and minimum or maximum
938 thresholds; and,
- 939 • Quantify annual changes in water budget components.

940 The monitoring network will have sufficient spatial density and temporal resolution to evaluate
941 the effects and effectiveness of plan implementation and represent seasonal, short-term, and
942 long-term trends in groundwater conditions and related surface conditions. For the purposes of
943 this Plan, short-term is considered a time span of 1 to 5 years, and long-term is considered to
944 be 5 to 20 years. The spatial densities and frequency of data measurement are specific to the
945 monitoring objectives, parameter measured, degree of groundwater use, and SV Subbasin
946 conditions.

947 Although "shallow" and "deep" aquifer terms have been historically used by DWR, analysis of
948 data from drilling records, water level response, groundwater chemistry and groundwater

949 temperature studies do not necessarily indicate two distinctive aquifers throughout the
950 groundwater Subbasin (see **Section 2.2.1.6**). Regardless, monitoring wells with adequate
951 vertical distribution are selected as RMPs to capture “shallow” and “deep” zones of the
952 production aquifer.

953 **Network Enrollment and Expansion**

954 Except for streamflow, land subsidence, and ISW depletion due to groundwater pumping,
955 monitoring is performed using networks of groundwater monitoring wells. In the case of land
956 subsidence and ISW depletion, although other monitoring and assessment approaches exist
957 (i.e., InSAR and elevation surveys; modeled ISW depletion rates and volumes), groundwater
958 level is also used as a proxy. Thus, groundwater monitoring wells are critical.

959 Some groundwater wells will be monitored for water level, some for water quality, and some will
960 be monitored for both. Each monitoring well in the network will be modified throughout GSP
961 implementation as necessary to address monitoring objectives and support projects and
962 management actions. Expansion of networks will involve identifying existing wells in the
963 Subbasin that can potentially be added to the network, applying selection criteria, and ultimately
964 approving the well for inclusion.

965 Evaluation of the monitoring networks will be conducted at least every 5 years to determine
966 whether additional wells are required to achieve sufficient spatial density, whether wells are
967 representative of Subbasin conditions, and whether wells cover key areas identified by
968 stakeholders. Prior to enrolling wells into the GSA’s monitoring network, wells are evaluated
969 using the following selection criteria: well location, monitoring history, well information, and well
970 access. These criteria are discussed below.

971 *Well Location*

972 Objectives for network design include sufficient coverage, density, and distribution of wells to
973 monitor groundwater storage, flow directions, and hydraulic gradients. Where monitoring wells
974 are not present, statistical methods are used to aid in extrapolating data from existing
975 monitoring sites to the entire Subbasin. Beyond capturing general hydrologic trends in the
976 Subbasin, it is important to monitor planned GSP projects and management actions, and
977 locations where existing or legacy operations may threaten groundwater quality for beneficial
978 uses and users.

979 *Monitoring History*

980 Wells with a long monitoring record provide valuable historical groundwater level and water
981 quality data and enable the assessment of long-term trends. Such wells are preferentially
982 selected over wells with limited monitoring data.

983 *Well Information*

984 Well construction information including well depth and screened interval are essential to
985 interpret monitoring results and ensure adequate vertical monitoring coverage of the aquifer. At
986 a minimum, selected wells should have well depth information. Although the perforated interval
987 is not available for all wells, it is essential to include these wells as potential wells to provide
988 adequate lateral coverage. For these wells, the GSAs will work to collect well information with
989 site surveys during the first year of GSP implementation.

990 *Well Access/Agency Support*

991 Ability to gain access to a well to collect samples at the required frequency is critical. When
992 necessary, the GSAs will coordinate with existing programs to develop an agreement for data

993 collection responsibilities, monitoring protocols, and data reporting and sharing. For existing
 994 monitoring programs implemented by agencies, monitoring will be conducted by agency
 995 program staff or their contractors. For groundwater elevation monitoring, a subset of wells
 996 included in the California Statewide Groundwater Elevation Monitoring (CASGEM) Program for
 997 Plumas County and Sierra County was selected and incorporated to the GSP monitoring
 998 network administered by the GSA. For water quality monitoring, samples will be analyzed at
 999 contracted analytical laboratories.

1000 **3.4.1 Monitoring Networks in the Subbasin**

1001 Based on the SV Subbasin’s historical and present-day conditions (**Section 2.2.2**), the
 1002 sustainability indicators that will be monitored include groundwater level and storage,
 1003 interconnected surface water, groundwater quality, and land subsidence. Seawater intrusion is
 1004 not found in the Subbasin and is therefore not monitored (23 CCR § 354.34(j)). Existing and
 1005 planned spatial density, and data collection frequency is now described for each monitoring
 1006 network. Descriptions, assessments, and plans for future improvement of the well monitoring
 1007 networks, along with protocols for data collection and monitoring are addressed for each
 1008 sustainability indicator in its corresponding subsection.

1009 As listed in **Table 3.4.1-1** there are four monitoring networks: a water level monitoring network,
 1010 a streamflow depletion monitoring network, a land subsidence monitoring system, and water
 1011 quality monitoring network (the groundwater storage network is monitored using the same wells
 1012 included in the groundwater elevation monitoring network). The water level and water quality
 1013 networks are independent but utilize some of the same wells. The land subsidence monitoring
 1014 system utilizes satellite remote sensing along with land-based survey monuments, and the
 1015 streamflow depletion monitoring network utilizes wells, **streamflow gauges**, and integrated
 1016 **hydrological model estimates** adapted throughout the implementation period based on available
 1017 data and tools.

1018 **Table 3.4.1-1. Summary of monitoring networks, metrics,**
 1019 **and number of sites for sustainability indicators**

| Sustainability Indicator ⁽¹⁾ | Metric | Number of RMPs in Current Network |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| Chronic Lowering of Groundwater Levels ⁽²⁾ | Groundwater level | 36 |
| Reduction of Groundwater Storage | Groundwater level as proxy; volume of water per year, computed by the forthcoming regional groundwater flow model | Uses chronic lowering of groundwater levels network |
| Stream Depletion due to Groundwater Pumping | Groundwater level as proxy; and ISW depletion rate and volume computed by the forthcoming regional groundwater flow model. Additionally, vertical hydraulic gradients will be measured at multi-completion wells and streamflow will be measured at stream gages. | 13 |
| Groundwater Quality | Concentration of selected water quality parameters | 17 confirmed; 14 pending (Table 3.3.4-2) |
| Land Subsidence | Groundwater level as proxy; DWR’s vertical displacement estimates derived | Spatially continuous |

| Sustainability Indicator ⁽¹⁾ | Metric | Number of RMPs in Current Network |
|-----------------------------------------|---------------------------------------------------------------------------|-----------------------------------|
| | from Interferometric Synthetic Aperture Radar (InSAR) data ⁽³⁾ | |

- 1020 (1) This table only includes monitoring networks used to measure sustainability indicators. It does not include
 1021 additional monitoring necessary to monitoring the various water budget components of the Subbasin, described
 1022 in Chapter 2, or to monitoring the implementation of projects and management actions, which are described in
 1023 Chapter 4.
- 1024 (2) The groundwater level monitoring network is also used for non-riparian groundwater dependent ecosystems.
- 1025 (3) Land surface elevation changes are monitored through satellite remote sensing and data processing is
 1026 assumed will be continued by DWR.

1027 **3.4.1.1 Groundwater Elevation Monitoring Network**

1028 The groundwater elevation monitoring network is designed to monitor groundwater occurrence,
 1029 level, flow directions, and hydraulic gradients between the aquifers and surface water bodies.

1030 The initial list of groundwater level monitoring wells included 130 wells. These wells were
 1031 narrowed down based on the following criteria:

- 1032 • Either depth or perforated interval are known, preferably both;
- 1033 • Measured water level data are available through at least 2019 (this criterion was relaxed
 1034 in locations where spatial coverage is lacking);
- 1035 • A preference was given to wells with data prior to 2005; and,
- 1036 • The well has at least five historical measurements.

1037 Annual pumping in the subbasin is between 1,000 and 10,000 acre-feet/year per 100 square
 1038 miles, resulting in a suggested density of 2 monitoring wells per 100 square miles to collect
 1039 representative groundwater elevation measurements (Hopkins 1984; DWR, 2016). Based on
 1040 this density consideration, and the Subbasin’s surface area of 195.1 square miles (combined
 1041 area of the SV Subbasin and Chilcoot Subbasin), 4 monitoring wells are adequate to monitor
 1042 representative groundwater elevations within the Subbasin.

1043 Alternatively, Sophocleous (1983) estimates 6.3 monitoring wells are needed per 100 square
 1044 miles, resulting in 12.3 monitoring wells needed in the Subbasin (Sophocleous, 1983; DWR,
 1045 2016). Based on this estimate, 13 wells will sufficiently monitor the Subbasin’s surface area of
 1046 195.1 square miles; equivalent to a lateral coverage of 15.0 square miles per well, or radius of
 1047 2.2-miles per well. The proposed groundwater elevation network (Error! Reference source not
 1048 found. and **Table 3.3.1-1**) uses 36 monitoring wells and covers 82% of the Subbasin (160.4 of
 1049 195.1 square miles) according to spatial coverage estimates by Sophocleous (1983).

1050 As stated, although “shallow” and “deep” aquifer terms have been historically used by DWR,
 1051 analysis does not necessarily indicate the presence of two distinct aquifers throughout the
 1052 Subbasin (**Section 2.2.1.6**); however, wells are selected to provide **adequate vertical coverage**
 1053 throughout the aquifer to reflect trends in the depths that are pumped. Importantly, the proposed
 1054 monitoring well density is appropriate to extrapolate seasonal groundwater elevation maps to
 1055 support analysis of impacts to shallow domestic wells, GDE impact analysis, and to monitor
 1056 seasonal changes in hydraulic gradients that may indicate changes in ISW depletion.
 1057 Implementation actions are proposed to cover data gaps in the network and make
 1058 improvements to existing RMPs

1059 Monitoring frequency is important to characterize groundwater and surface water dynamics. All
1060 wells will collect at least biannual measurements in spring (mid-March) and fall (mid-October) in
1061 line with DWR Best Management Practices (DWR, 2016). Monitoring standards and
1062 conventions are consistent with 23 CCR § 352.4, which outline data and reporting standards for
1063 groundwater level measurements.

1064 *3.4.1.1.1 Protocols for Data Collection and Monitoring (23 CCR § 352.2)*

1065 This subsection briefly summarizes monitoring protocols. Groundwater level data collection may
1066 be conducted remotely via telemetry equipment, or with an in-person field crew. This subsection
1067 provides a brief summary of monitoring protocols. Establishment of protocols will ensure that
1068 data collected for groundwater elevation are accurate, representative, reproducible, and contain
1069 all required information. All groundwater data collection in support of this GSP is required to
1070 follow the established protocols for consistency throughout the basin and over time. These
1071 monitoring protocols will be updated as necessary and will be re-evaluated every five years. All
1072 groundwater elevation measurements are references to a consistent datum, known as the
1073 Reference Point (RP). For monitoring wells, the RP consists of a mark on the top of the well
1074 casing. For most production wells, the RP is the top of the well's concrete pedestal. The
1075 elevation of the RP of each well is surveyed to the National Geodetic Vertical Datum of 1929
1076 (NDVD 29). The elevation of the RP is accurate to at least 0.5 feet.

1077 Groundwater level measurements are taken to the nearest 0.01 foot relative to the RP using
1078 procedures appropriate for the measuring device. Equipment is operated and maintained in
1079 accordance with manufacturer's instructions, and all measurements are consistent units of feet,
1080 tenths of feet, and hundredths of feet.

1081
1082
1083

Figure 3.4.1-1. RMPs for the Groundwater Level Monitoring Network
(Network coverage is depicted with blue, circular 15.0 square mile buffers around each monitoring point that show the 82% lateral coverage of the network)

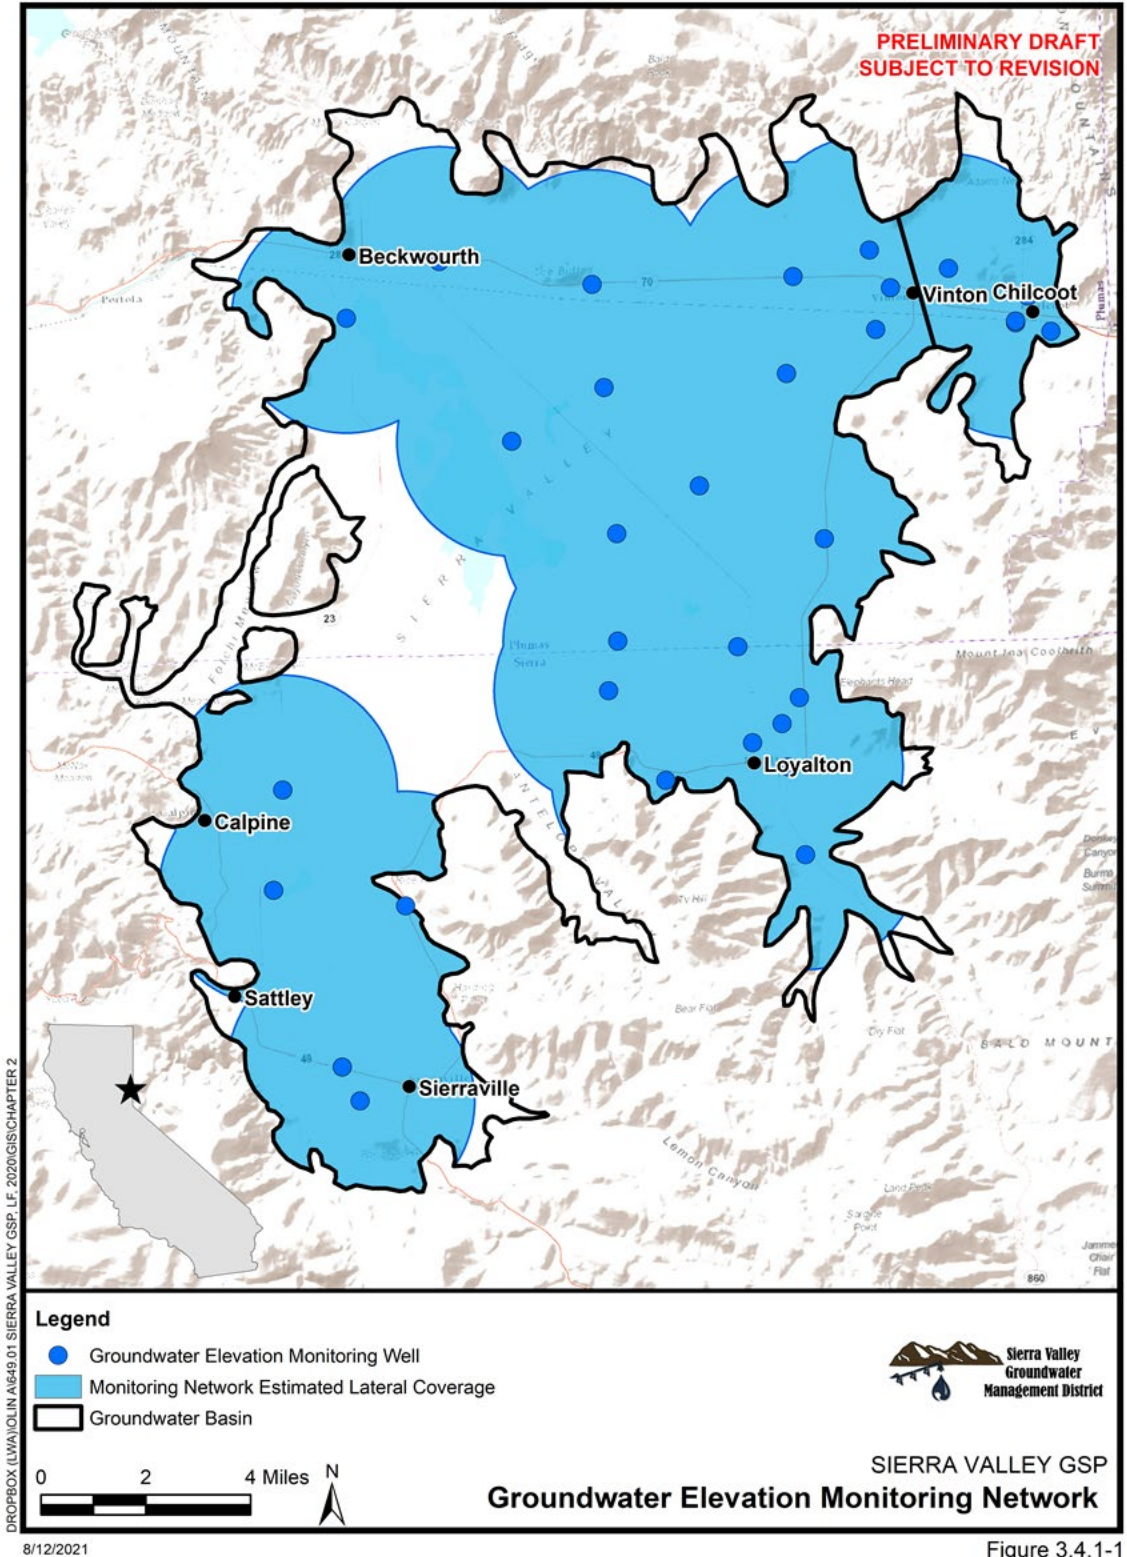

Figure 3.4.1-1

1084 Groundwater elevation is calculated using the following equation:

1085
$$GWE = RPE - DTW$$

1086 Where GWE is the groundwater elevation, RPE is the reference point elevation, and DTW is the
1087 depth to water. When available, barometric pressure is also accounted for in the depth to water
1088 calculation.

1089 In cases where the official RPE is a concrete pedestal, but the hand soundings are referenced
1090 off the top of a sounding tube, the measured DTW is adjusted by subtracting the sounding tube
1091 offset from the top of the pedestal.

1092 All groundwater level measurements must include a record of the date, well identifier, time
1093 (in 24-hour military format), RPE, DTW, GWE, and comments regarding factors which may
1094 influence the recorded measurement such as nearby production wells pumping, weather,
1095 flooding, or well condition.

1096 **Manual Groundwater Level Measurement**

1097 Groundwater level data collected by an in-person field crew will follow the following general
1098 protocols:

- 1099 • Prior to sample collection, all sampling equipment and the sampling port must be
1100 cleaned.
- 1101 • Manual groundwater level measurements are made with electronic sounders or steel
1102 tape. Electronic sounders consist of a long, graduated wire equipped with a weighted
1103 electric sensor. When the sensor is lowered into water, a circuit is completed and an
1104 audible beep is produced, at which point the sampler will record the depth to water.
1105 Some production wells may have lubricating oil floating on the top of the water column,
1106 in which case electric sounders will be ineffective. In this circumstance steel tape may be
1107 used. Steel tape instruments consist of simple graduated lines where the end of the line
1108 is chalked to indicate depth to water without interference from floating oil.
- 1109 • All equipment is used following manufacturer specifications for procedure and
1110 maintenance.
- 1111 • Measurements must be taken in wells that have not been subject to recent pumping. At
1112 least 2 hours of recovery must be allowed before a hand sounding is taken.
- 1113 • For each well, multiple measurements are collected to ensure the well has reached
1114 equilibrium such that no significant changes in groundwater level are observed.
- 1115 • Equipment is sanitized between well locations to prevent contamination and maintain the
1116 accuracy of concurrent groundwater quality sampling.

1117 **Data Logger Groundwater Level Measurement**

1118 Telemetry equipment and data loggers can be installed at individual wells to record continuous
1119 water level data, which is then remotely collected via satellite to a central database and
1120 accessed on the Sierra Valley Database Portal in a web browser. Installation and use of data
1121 loggers must abide by the following protocols:

- 1122 • Prior to installation the sampler uses an electronic sounder or steel tape to measure and
1123 calculate the current groundwater level to properly install and calibrate the transducer.
1124 This is done following the protocols listed above.

- 1125 • All data logger installations follow manufacturer specifications for installation, calibration,
1126 data logging intervals, battery life, and anticipated life expectancy.
- 1127 • Data loggers are set to record only measured groundwater level to conserve data
1128 capacity; groundwater elevation is calculated later after downloading.
- 1129 • In any log or recorded datasheet, site photographs, the well ID, transducer ID,
1130 transducer range, transducer accuracy, and cable serial number are all recorded.
- 1131 • The field staff notes whether the pressure transducer uses a vented or non-vented cable
1132 for barometric compensation. If non-vented units are used, data are properly corrected
1133 for natural barometric pressure changes.
- 1134 • All data logger cables are secured to the well head with a well dock or another reliable
1135 method. This cable is marked at the elevation of the reference point to allow estimates of
1136 future cable slippage.
- 1137 • Data logger data is periodically checked against hand measured groundwater levels to
1138 monitor electronic drift, highlight cable movement, and ensure the data logger is
1139 operating correctly. This check occurs at least annually, typically during routine site
1140 visits.
- 1141 • For wells not connected to a supervisory control and data acquisition (SCADA) system,
1142 transducer data is downloaded as necessary to ensure no data is overwritten or lost.
1143 Data is entered into the data management system as soon as possible. When the
1144 transducer data is successfully downloaded and stored, the data is deleted or
1145 overwritten to ensure adequate data logger memory.

1146 **3.4.1.2 Groundwater Storage Monitoring Network**

1147 Groundwater level is used as a proxy for groundwater storage (**Section 3.3.1.6.1**) and therefore
1148 the groundwater storage monitoring network is identical to the network for groundwater level.
1149 Observations obtained at the groundwater level monitoring network will directly inform
1150 integrated surface and groundwater modeling in the subbasin as model calibration targets.

1151 **3.4.1.3 Groundwater Quality Monitoring Network**

1152 The objective of the groundwater quality monitoring network design is to capture sufficient
1153 spatial and temporal detail to understand groundwater quality in the Subbasin. The purpose is
1154 also to adequately monitor groundwater conditions for all beneficial uses. The data from the
1155 network will provide an ongoing water quality record for future assessments of groundwater
1156 quality. The spatial and temporal coverage of the network is designed to allow the GSAs to take
1157 an effective and efficient adaptive management approach in protecting groundwater quality, to
1158 minimize the risk for exceeding maximum water quality thresholds, to support the GSAs in
1159 implementing timely projects and actions, and ultimately, to contribute to compliance with water
1160 quality objectives throughout the Subbasin.

1161 Existing wells used to monitor groundwater quality in the Subbasin are primarily located within
1162 and near the semi-urban areas of the Subbasin. Additionally, members of the community
1163 volunteered eight wells to potentially be included in the network; these volunteered wells do not
1164 have a historical record of water quality data. There are data gaps in the Subbasin regarding the
1165 spatial and temporal distribution of groundwater quality data. For this reason, five new
1166 monitoring wells will be installed as part of the network. These new wells will be incorporated
1167 into the network to improve spatial coverage of the Subbasin; one additional well installed by
1168 DWR will also be incorporated into the network.

1169 The monitoring network will use existing programs in the Subbasin that already monitor for
1170 specific constituents of concern for which SMCs are set (nitrate and TDS), and from other
1171 programs where these constituents could be added as part of routine monitoring efforts in
1172 support of the GSP. Coordination will be conducted between existing monitoring programs and
1173 the GSAs to develop an agreement for data collection responsibilities, monitoring protocols, and
1174 data reporting. Samples for nitrate, TDS, arsenic, boron, and pH will be collected at least
1175 **annually** from each well in the water quality network. To prevent bias associated with date of
1176 sample collection, all samples should be collected on approximately the **same date (i.e.,**
1177 **+/- 30 days of each other) each year**. Groundwater quality samples will be collected and
1178 analyzed in accordance with the monitoring protocols outlined in below.

1179 Using the geographic location of wells with historic groundwater quality records (June 1990 –
1180 July 2020), an initial list of wells with groundwater quality measurements was created for
1181 inclusion in the monitoring network. Water quality monitoring well locations were then reviewed
1182 to assess the spatial coverage obtained from the network. Information on the screened interval
1183 and well depth was scarce. This data gap will be addressed through further investigation of well
1184 completion reports and use of well video logs. Spatial data gaps, and potentially inadequate
1185 vertical coverage, will be addressed through the installation of new wells. Additionally, future
1186 project and management actions outlined in **Chapter 4** will be implemented to refine the water
1187 quality network as needed.

1188 The initial list of groundwater quality monitoring wells was created using data downloaded from
1189 the California Groundwater Ambient Monitoring and Assessment (GAMA) Program Database,
1190 which for the Sierra Valley Subbasin includes water quality information collected by the following
1191 agencies:

- 1192 • Department of Water Resources (DWR)
- 1193 • State Water Board, Division of Drinking Water public supply well water quality (DDW)
- 1194 • State and Regional Water Board Regulatory Programs (Electronic Deliverable Format
1195 (EDF) and Irrigated Agricultural Land Waiver (AGLAND))
- 1196 • U.S. Geological Survey (USGS)

1197 Evaluating these data, the initial list of groundwater quality monitoring wells includes 53 wells
1198 with historical data for both nitrate and TDS. To further narrow down the number of wells, the
1199 following criteria were considered (it is noted criteria were relaxed in some instances so as to
1200 provide better spatial coverage):

- 1201 • Both nitrate and TDS measured at the same well;
- 1202 • Measured water quality data are available at least through 2019; and,
- 1203 • The well has at least two historical measurements.

1204 Wells that met this criterion were then narrowed down to avoid inclusion of redundant
1205 monitoring wells that were within proximity to each other. As shown in **Figure 3.4.1-2** and
1206 **Table 3.4.1-2**, the final network includes 17 GAMA wells for potential inclusion in the network.
1207 While there is no definitive rule for the appropriate density of groundwater quality monitoring
1208 points needed in a basin, Sophocleous (1983) estimates 6.3 monitoring wells are needed per
1209 100 square miles to adequately monitor groundwater levels in a basin, resulting in an estimated
1210 12.3 monitoring wells needed in the SV subbasin (Sophocleous, 1983; DWR, 2016). Based on
1211 Sophocleous (1983), 13 wells are needed to monitor the subbasin's surface area of

1212 195.1 square miles; equivalent to a lateral coverage of 15.0 square miles per well, or radius of
1213 2.2 miles per well.

1214 **Table 3.4.1-2. Potential GAMA Wells to be added to the Groundwater Quality Monitoring Network**
1215 **(Measurement period 1990-2020)**

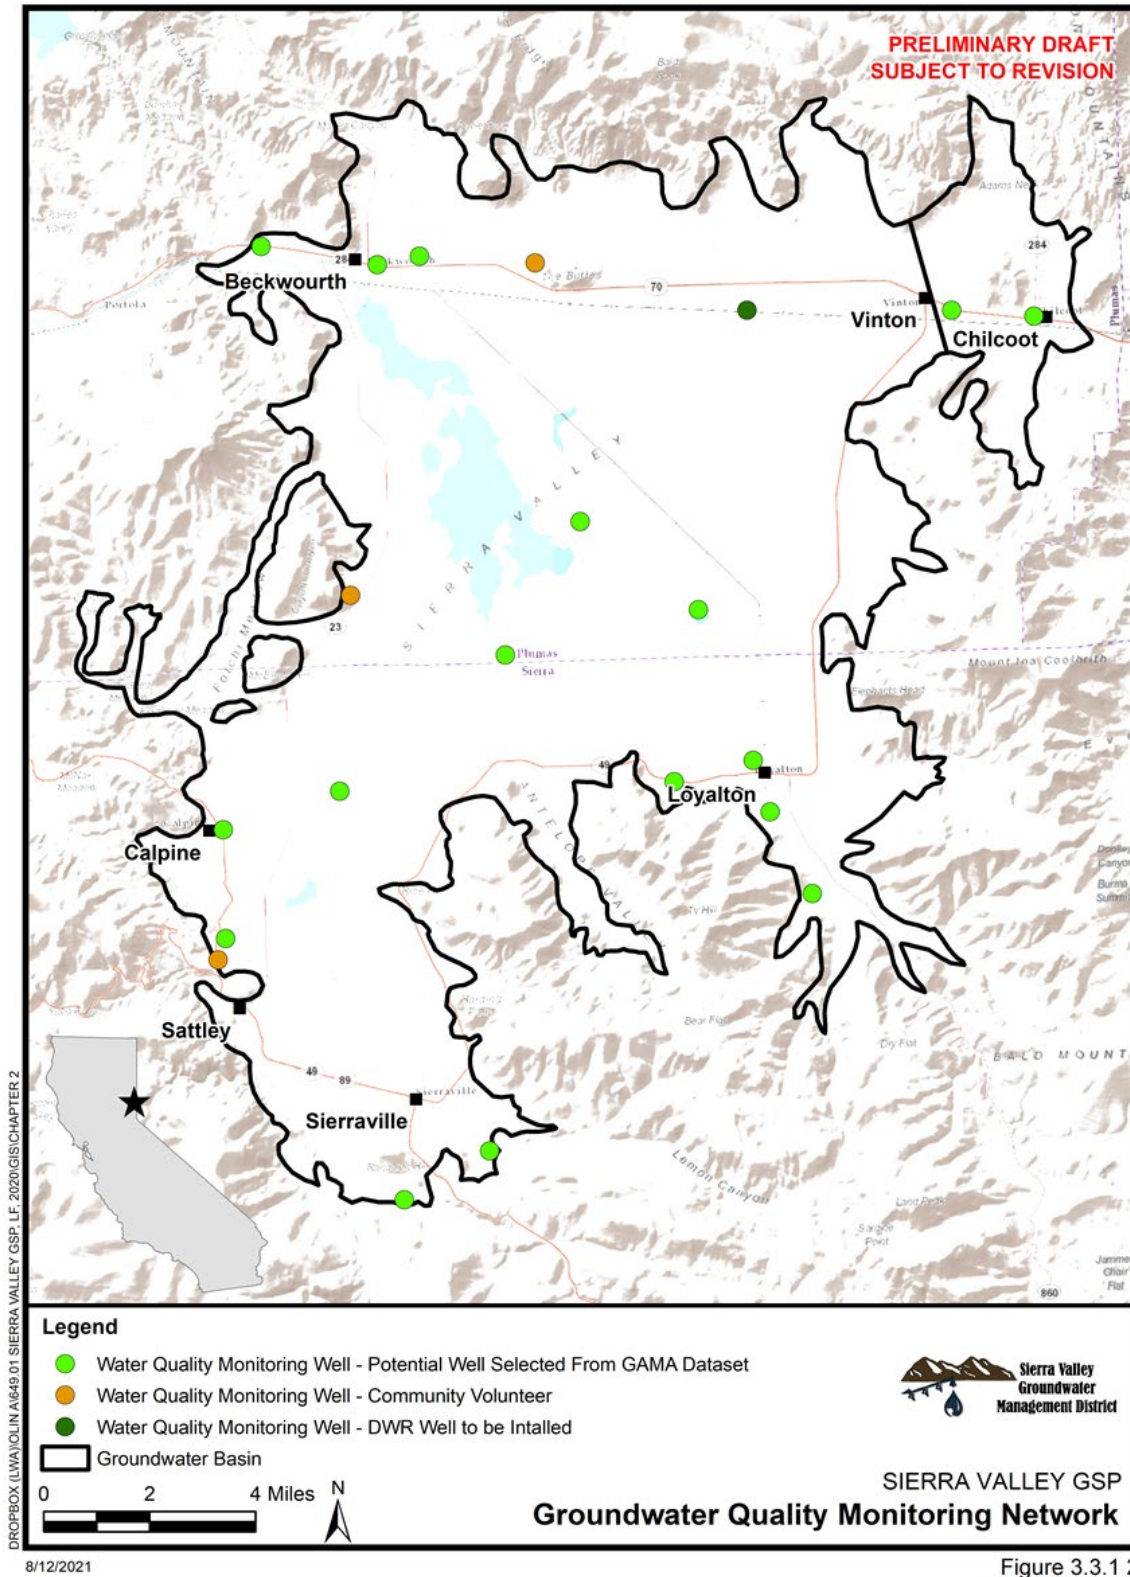

Figure 3.3.1.2

1217 **3.4.1.3.1 Monitoring Protocols for Data Collection and Monitoring (Reg. § 352.2)**

1218 Sample collection will follow the USGS National Field Manual for the Collection of Water Quality
1219 Data (USGS 2015) and Standard Methods for the Examination of Water and Wastewater (Rice
1220 et al., 2012), as applicable, in addition to the general sampling protocols listed below.

1221 The following section provides a summary of monitoring protocols for sample collection and
1222 analytical testing for evaluation of groundwater quality. Establishment of and adherence to these
1223 protocols will ensure that data collected for groundwater quality are accurate, representative,
1224 reproducible, and contain all required information. All sample collection and testing for water
1225 quality in support of this GSP are required to follow the established protocols for consistency
1226 throughout the Subbasin and over time. All testing of groundwater quality samples will be
1227 conducted by laboratories with certification under the California Environmental Laboratory
1228 Accreditation Program (ELAP). These monitoring protocols will be updated as necessary and
1229 will be re-evaluated every 5 years.

1230 Wells used for sampling are required to have a distinct identifier, which must be located on the
1231 well housing or casing. This identifier will also be included on the sample container label to
1232 ensure traceability.

1233 **Event Preparation:**

1234 • Before the sampling event, coordination with any laboratory used for sample analysis is
1235 required. Pre-sampling event coordination must include the scheduling of the laboratory
1236 for sample testing and a review of the applicable sample holding times and preservation
1237 requirements that must be observed.

1238 • Sample labels must include the sample ID, well ID, sample date and time, personnel
1239 responsible for sample collection, any preservative in the sample container, the analyte
1240 to be analyzed, and the analytical method to be used. Sample containers may be
1241 labelled prior to or during the sampling event.

1242 **Sample Collection and Analysis:**

1243 • Sample collection must occur at, or close to, the wellhead for wells with dedicated
1244 pumps and may not be collected after any treatment, from tanks, or after the water has
1245 travelled through long pipes. Prior to sample collection, the sample collector should
1246 clean all sampling equipment and the sampling port. The sampling equipment must also
1247 be cleaned prior to use at each new sample location or well.

1248 • Sample collection in wells with low-flow or passive sampling equipment must follow
1249 protocols outlined in the EPA's Low-flow (minimal drawdown) ground-water sampling
1250 procedures (Puls and Barcelona, 1996) and USGS Fact Sheet 088-00 (USGS, 2000),
1251 respectively. Prior to sample collection in wells without low-flow or passive sampling
1252 equipment, at least three well casing volumes should be purged prior to sample
1253 collection to make sure ambient water is being tested. The sample collector should use
1254 best professional judgement to ensure that the sample is representative of ambient
1255 groundwater. If a well goes dry, this should be noted, and the well should be allowed to
1256 return to at least 90% of the original level before a sample is collected.

1257 • Sample collection should be completed under laminar flow conditions.

1258 • Samples must be collected in accordance with appropriate guidance and standards and
1259 should meet specifications for the specific constituent analyzed and associated data
1260 quality objectives.

- 1261 • In addition to sample collection for the target analyte (e.g., nitrate), field parameters,
1262 including temperature, pH, and specific conductivity, must be collected at every site
1263 during well purging. Field parameters should stabilize before being recorded and before
1264 samples are collected. Field instruments must be calibrated daily and checked for drift
1265 throughout the day.
- 1266 • Samples should be chilled and maintained at a temperature of 4° C and maintained at
1267 this temperature through delivery to the laboratory responsible for analysis.
- 1268 • Chain of custody forms are required for all sample collection and must be delivered to
1269 the laboratory responsible for analysis of the samples to ensure that samples are tested
1270 within applicable holding limits.
- 1271 • Laboratories must use reporting limits that are equivalent, or less than, applicable data
1272 quality objectives.

1273 **3.4.1.4 Depletions of Interconnected Surface Water Monitoring Network**

1274 The ISW depletion monitoring network, shown in **Figure 3.4.1-3**, is developed to document
1275 streamflow and hydraulic gradients within the Sierra Valley and incorporates groundwater level
1276 RMPs, and monitoring sites for streamflow, and stream stage. The combination of these
1277 monitoring networks will allow for a better understanding of the surface-groundwater
1278 interactions, permit calculation of streamflow depletion its spatial and temporal distribution, and
1279 will provide important context for understanding the effects of pumping on surface water that is
1280 critical for priority species. To evaluate the potential impacts of groundwater pumping on surface
1281 water depletion, groundwater level, stream stage, and streamflow conditions will be documented
1282 over time at representative monitoring points.

1283 ISW depletion monitoring in the Sierra Valley will involve two approaches: 1) measuring
1284 relatively shallow groundwater and its relationship to surface water elevation ('stage') for
1285 calculation of hydraulic gradients between streams and groundwater, and 2) monitoring
1286 streamflow. As described in **subsection 3.3.3.4.1**, stage data are not currently being collected,
1287 so groundwater levels are proposed as a proxy for hydraulic gradients, and by extension, for
1288 ISW depletion, until surface water monitoring stations can be established. Similarly, the
1289 absence of near-continuous streamflow gaging stations prevents direct measurement of
1290 streamflow changes due to pumping under current conditions. The shallow groundwater
1291 monitoring network will therefore initially consist of existing wells which are screened at shallow
1292 depths (**Table 3.3.3-1**), some of which are also included in the groundwater level monitoring
1293 network.

1294 Strategically located new wells and stream stage and/or streamflow monitoring stations are also
1295 proposed, so that each ISW RMP located in **Figure 3.3.3-1** consists of a coupled surface water
1296 and shallow groundwater monitoring station for eventual calculation and tracking of hydraulic
1297 gradients in the vicinity of representative ISWs. The proposed new wells are intended to provide
1298 shallow groundwater level data in data gaps, and where groundwater level declines due to
1299 pumping have been documented. This information, used in conjunction with the basin
1300 groundwater model, will allow for a spatial and temporal quantification of ISW depletion.

1301

Table 3.4.1-3. Proposed stream stage gages and coupled wells to monitor ISW depletion

| Stream Stage Gage | General Location | Coupled Well |
|------------------------------------------------------------------------------|------------------------------------------------------|-----------------------------------------------------------------------------------|
| Middle Fork Feather River | At Marble Hot Springs Road | RMP ID 106 (22N15E17H001M) if active or a proposed new well in a similar location |
| Middle Fork Feather River (Flow also measured here) | Downstream of Little Last Chance Creek confluence | RMP ID 161 (23N14E35L001M) and RMP ID 301 (DMW 6s) |
| Smithneck Creek | Between Highway 49 and Poole Lane | RMP ID 73 (21N16E18G002M) and RMP ID 37 (DMW 1s) |
| Central Wetland Complex | West of Harriet Lane south of Dyson Lane | Proposed new shallow well 1 |
| Sierra Valley Channels | West of Highway 49 near Rice Hill | RMP ID 31 (21N14E25P003M) and RMP ID 294 (DMW 3s) |
| Carman Creek | Near Westside Road | RMP ID 297 (DMW 4s) |
| Hamlin Creek (Flow also measured here) | South of Willow Street on Forest Service Road 54020 | RMP ID 291 (DMW 2s) |
| Cold Stream (Flow also measured here) | Downstream of Bonta Creek and upstream of diversions | RMP ID 12 (20N14E14R001M) |
| East Channel LLC Creek | At Sierra Valley Mc Nella Lane | Proposed new shallow well 1 |
| East Channel LLC Creek | East of Roberti Ranch Road | RMP ID 364 (DMW 7s) |
| North Channel LLC Creek | South of Highway 70 near The Buttes | RMP 176 (23N15E34D001M) |
| Little Last Chance Creek East and West Branches (Flow also measured here) | At Highway 70 | Proposed new shallow well 2, RMP ID 209 (23N16E36N002M), and RMP 300 (DMW 5s) |

1302 In addition to shallow groundwater and surface water stage monitoring, near-continuous
 1303 recording streamflow gages are an integral part of the ISW depletion monitoring program.
 1304 Streams and numerous diversion ditches are vast, and in-situ monitoring of every ISW is
 1305 impractical. Therefore continuous streamflow monitoring gages are proposed as upgrades to
 1306 the existing DWR streamflow monitoring stations (i.e., where major tributaries enter the Basin),
 1307 and at select locations where flow concentrates. This approach captures much of the flow
 1308 entering the basin and can be used to calibrate modeled estimates of total surface inflows, as
 1309 well as depletion estimates as these streams cross the valley floor. Final locations of proposed
 1310 wells, streamflow stages, and streamflow gages will be determined by a site suitability study,
 1311 where physical characteristics of the stream and site accessibility will be evaluated.

1312

Table 3.4.1-4. Proposed streamflow gages to monitor ISW depletion

| Streamflow Gage | General Location | Notes |
|-------------------------------------------------|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Little Last Chance Creek East and West Branches | At Highway 70 | Two existing but inactive DWR gaging stations exist here and would be reoccupied and upgraded |
| Smithneck Creek | Upstream of Loyalton | Watermaster streamflow monitoring site would be upgraded to a near-continuous recording gaging station |
| Fletcher Creek | West of Calpine | Watermaster streamflow monitoring site would be upgraded to a near-continuous recording gaging station |
| Turner Creek | Northwest of Sattley | Watermaster streamflow monitoring site would be upgraded to a near-continuous recording gaging station |
| Berry (Miller) Creek | West of Highway 49 in Wild Bill Canyon | Watermaster streamflow monitoring site would be upgraded to a near-continuous recording gaging station |
| Hamlin Creek | South of Willow Street on Forest Service Road 54020 | Watermaster streamflow monitoring site would be upgraded to a near-continuous recording gaging station |
| Cold Stream | Downstream of Bonta Creek and upstream of diversions | This would combine the Bonta (Webber) Creek stations to one station below the confluence of the two creeks, provided that this would not interfere with Little Truckee Diversion operations. |
| Lemon Creek | At Lemon Canyon Road (650) | Watermaster streamflow monitoring site would be upgraded to a near-continuous recording gaging station |
| Middle Fork Feather River | Downstream of Little Last Chance Creek confluence | Watermaster streamflow monitoring site would be upgraded to a near-continuous recording gaging station |

1313 Data collected from the monitoring network will allow for evaluation of minimum thresholds and
 1314 undesirable results and whether adjustments will be needed at the five year GSP review. After
 1315 this initial five years of GSP implementation, the use of groundwater levels and hydraulic
 1316 gradients as a proxy for surface water depletion will also be reevaluated to determine if the
 1317 approach is a beneficial addition to direct streamflow measurements and still an appropriate
 1318 metric for the sustainability indicator. Minimum thresholds and measurable objectives will be
 1319 reviewed and adjustments will be made as needed.

1320
1321

Figure 3.4.1-3. Existing ISW monitoring locations for flow, stage, and groundwater level are shown alongside ISW characterization at prominent surface water bodies

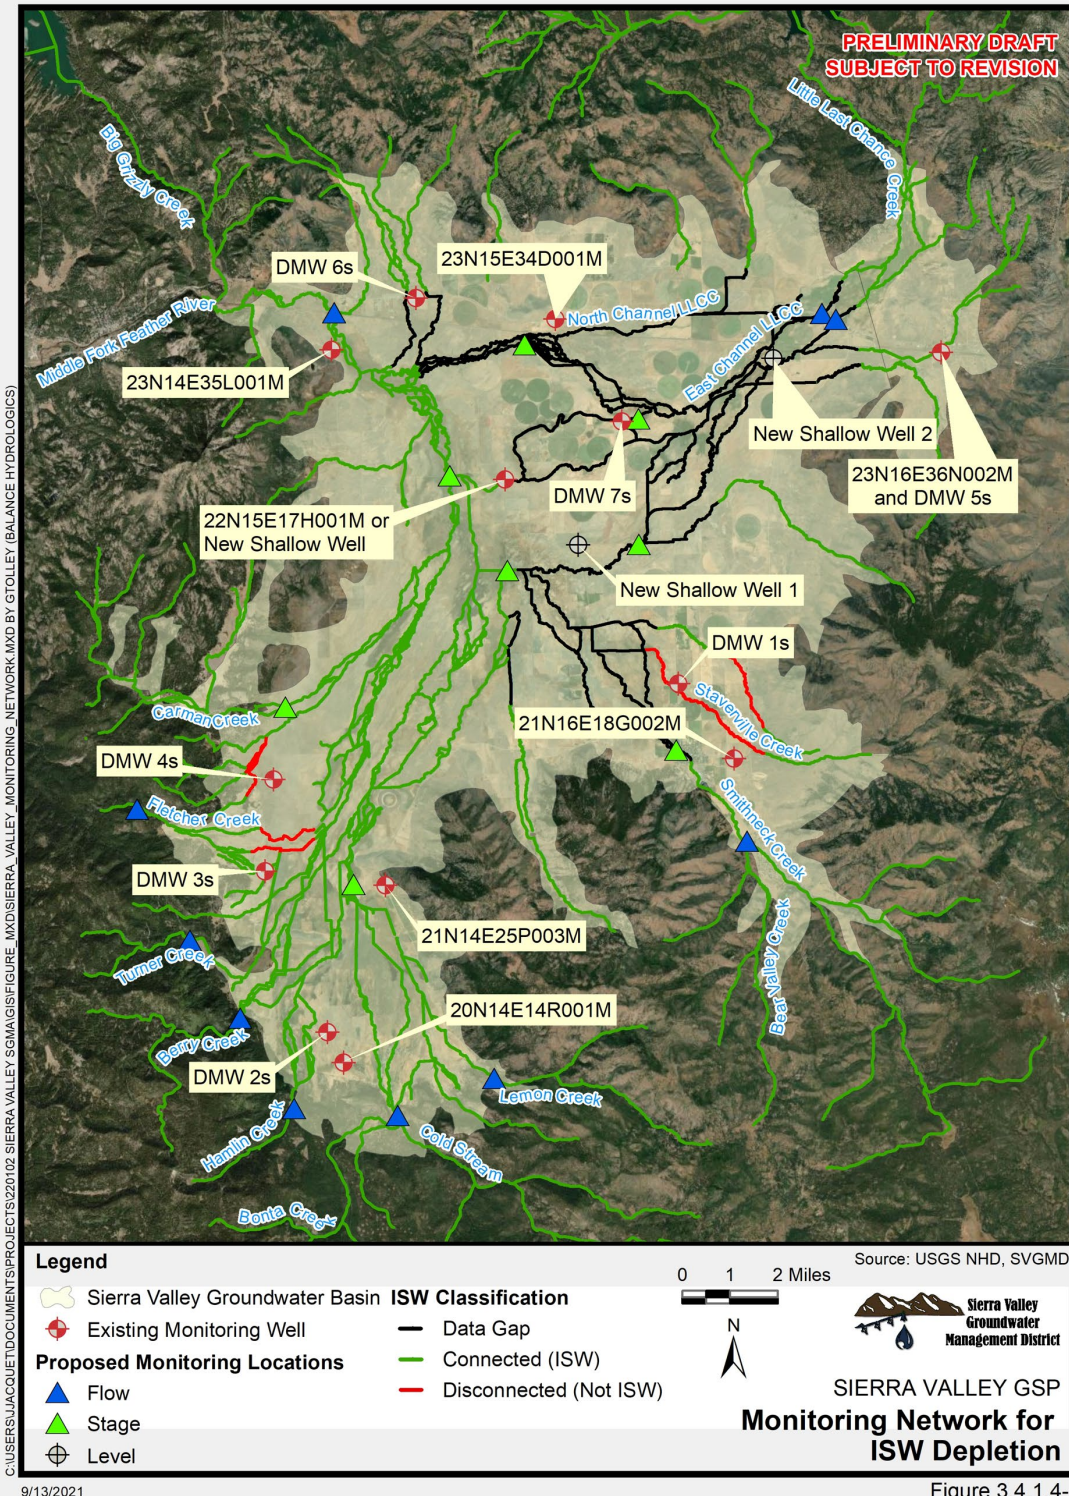

Figure 3.4.1.4-1

1322

1323 3.4.1.4.1 *Protocols for Data Collection and Monitoring (23 CCR § 352.2)*

1324 **Groundwater Level Measurement**

1325 See **subsection 3.4.1.1.1** for protocols for monitoring of groundwater levels.

1326 **Measurement of Continuous Stage and Streamflow**

- 1327 • Stream-gaging practices will follow the procedures used by the USGS, as outlined by
- 1328 Carter and Davidian (1968).
- 1329 • Installation of streamflow gages will be based on reach specific characteristics and
- 1330 ideally located upstream of a natural or constructed grade control to maintain the
- 1331 relationship between stage and streamflow
- 1332 • Installation and instrumentation will include a ‘Style C’ staff plate that displays stage
- 1333 in decimal feet and is secured to a wood or metal post driven into the bed of the
- 1334 stream. A near-continuous water level logger will accompany the staff plate and will
- 1335 measure water depths in 15-minute intervals. If an unvented logger is used, a
- 1336 barometer will need to be installed at one of the stream gaging locations to
- 1337 compensate data for changing barometric pressure
- 1338 • Flow will be measured a minimum of 5 times annually over a range of different water
- 1339 depths (‘stages’).
- 1340 • Based on these periodic site visits where staff plate readings and streamflow
- 1341 measurements are made, an empirical stage-to-discharge relationship will be developed
- 1342 and adjusted over time for each station, also referred to as a stage-discharge “rating
- 1343 curve.” The rating curve will be used to convert the continuous-logging record of stage to
- 1344 flow.
- 1345 • The data will be analyzed, and if necessary, stage shifts will be applied to account for
- 1346 local scour and fill during the monitoring period, and the effects of leaf and debris dams
- 1347 during low flows, or effects of snow and ice in the winter.

1348 **3.4.1.5 Subsidence Monitoring Network**

1349 As per 23 CCR § 354.36(b), this GSP adopts groundwater elevations as a proxy for monitoring
1350 changes in groundwater in land subsidence. Groundwater levels are the only long-term
1351 measure of land subsidence for the Subbasin at the time of writing. Poland and Davis (1969)
1352 report the land subsidence to groundwater level decline ratio as approximately 0.01 to 0.2 foot
1353 of subsidence per foot of groundwater level decline. These land subsidence SMC will be
1354 augmented by InSAR based land elevation change, and ground-based surveys. Throughout the
1355 GSP implementation period, the relationship between the change in groundwater levels and the
1356 change in the amount land subsidence (factoring in that total land subsidence is a composite of
1357 elastic and inelastic land subsidence) will be developed.

1358 Management areas are not planned for this GSP at this time. The monitoring network applies to
1359 the entire Subbasin area.

1360 **3.4.1.5.1 Monitoring Protocols for Data Collection and Monitoring for Land Subsidence**
1361 **Sustainability Indicator (Reg. § 352.2)**

1362 As groundwater elevation measurements are to be used as a proxy for inelastic land
1363 subsidence in this GSP, the monitoring network for the land subsidence sustainability indicator
1364 is the same as the groundwater level monitoring network. The protocols used for the
1365 groundwater level monitoring network described in **Subsection 3.4.1.1** are the same for the
1366 land subsidence monitoring network.

1367 Four (4) monument-based land surface elevation stations will be installed within the primary
1368 geographic area where subsidence is documented by DWR from InSAR data processing for

1369 2015-2019. The subsidence monument placements will also be developed in consideration of
1370 geologic discontinuities, such as the Grizzly Valley Fault Zone. At these geologic
1371 discontinuities, there is the greatest potential for differential subsidence, which is normally the
1372 most damaging to structures and improvements such as roads or underground utilities.

1373 A licensed Professional Surveyor in the state of California will install the monuments. The
1374 monuments will be a deep rod construction type applicable to soils and land surface conditions
1375 at installation locations. Monument installation will follow industry guidelines for vertical control
1376 monument installation as documented in the US Army Corps of Engineers Guidance Document
1377 EM 1110-1-1002, (USACE, March 2012). Monument vertical elevations will be measured
1378 annually using survey-grade GPS technology, with vertical resolution of 0.05 ft, with elevations
1379 reported as feet above sea level using a standardized datum. Initial elevation measurements will
1380 be made at least 28 days after installation.

1381 The monument elevations will be used to gauge the accuracy of future InSAR data processing,
1382 and to calibrate the processing if needed. The data monument-based measurements may
1383 enable differentiation of inelastic and elastic components of land subsidence, if monuments are
1384 located near to monitoring well locations where depth to groundwater levels are being measured
1385 and some variance in depths to groundwater up and down is recorded (rebound in groundwater
1386 levels can be associated with rebound, or lack thereof, in land surface).

1387 *3.4.1.5.2 Representative Monitoring for Land Subsidence Sustainability Indicator*
1388 *(Reg. § 354.36)*

1389 As groundwater elevation measurements are to be used as a proxy for inelastic land
1390 subsidence in this GSP, the monitoring network for the land subsidence sustainability indicator
1391 is the same as the groundwater level monitoring network. Therefore, the representative
1392 monitoring sites within the groundwater elevation monitoring network, discussed in detail in
1393 **Subsection 3.4.1.1**, are identical to the monitoring network for the land subsidence
1394 sustainability indicator.

1395 *3.4.1.5.3 Assessment and Improvement of Monitoring Network for Land Subsidence*
1396 *Sustainability Indicator (Reg. § 354.38)*

1397 As groundwater elevation measurements are to be used as a proxy for inelastic land
1398 subsidence in this GSP, the monitoring network for the land subsidence sustainability indicator
1399 is the same as the groundwater level monitoring network discussed in detail in
1400 **Subsection 3.4.1.1**.

1401 InSAR and ground-based elevation surveys will augment groundwater level measurements and
1402 contribute towards improved understanding of land subsidence in the basin. Pending results
1403 from these analyses, the monitoring network may be improved in the five-year plan update.

1404 **3.4.2 Assessment and Improvement of the Monitoring Network (23 CCR § 354.38)**

1405 The GSP and each five-year assessment report will include an evaluation of the monitoring
1406 networks, including a determination of uncertainty and whether there are data gaps that could
1407 affect the ability of the Plan to achieve the sustainability goal for the Subbasin. Evaluation of
1408 data gaps must consider whether the spatial and temporal coverage of data is sufficient and
1409 whether monitoring sites provide reliable and representative data. The description of identified
1410 data gaps will include the location and basis for determining data gaps in the monitoring network
1411 as well as local issues and circumstances that limit or prevent monitoring. These data gaps will
1412 be addressed by describing steps that will be taken to fill data gaps before the next five-year
1413 assessment, including the location and purpose of newly added or installed monitoring sites.

1414 **3.4.3 Reporting Monitoring Data to the Department (23 CCR § 354.40, § 352.4)**

1415 Monitoring data will be stored in the data management system and a copy of the monitoring
1416 data will be included in each Annual Report submitted electronically to DWR. All reporting
1417 standards and information shall follow the guidelines outlined in 23 CCR § 352.4.
